

# **Support Document for the Development of Generic Numerical Standards and Risk Assessment Procedures**

**The Voluntary Action Program**  
Division of Emergency and Remedial Response  
Ohio Environmental Protection Agency

February 2002

**This document was prepared as a supplemental guidance to accompany the administrative rules for the Ohio Environmental Protection Agency Voluntary Action Program concerning Generic Numerical Standards (Rule 3745-300-08 of the Ohio Administrative Code) and Property-Specific Risk Assessment Procedures (Rule 3745-300-09 of the Ohio Administrative Code). This guidance is effective upon the adoption of these rules and all other Voluntary Action Program rules filed with the Ohio General Assembly Joint Committee on Agency Rule Review on March 1, 2002 into Section 3745-300 of the Ohio Administrative Code.**

**Please direct any questions, comments or requests for technical assistance to:**

**SECTION I:**

**Determination of Exposure, Intake and Generic and Property-Specific  
Numerical Standards**

**I. Calculation of Generic Direct-Contact Soil Standards for chemicals listed in Tables II-IV of the Generic Numerical Standards Rule (3745-300-08), and Property-Specific Standards as Described in Rule 3745-300-09:**

The Generic Direct Contact Soil Standards listed in Tables II-IV of the Generic Numerical Standards Rule, rule 3745-300-08 of the Ohio Administrative Code, have been calculated probabilistically, utilizing Monte Carlo Simulation (MCS) as a technique to model heterogeneous human receptor populations exposed through each of three potential land use category exposure scenarios (residential, commercial, or industrial). In addition, generic direct-contact soil standards based upon exposures during construction or excavation activities have been derived. In instances where generic numerical cleanup standards have not been calculated, this approach, or a more traditional deterministic approach using single point values may be employed. Regardless of approach, probabilistic or point value, however, there are several underlying mathematical models common to either approach, all of which are intended to describe: (1) how chemicals in the soil travel to a receptor; (2) how those chemicals traverse epithelial barriers to gain entrance to the body of a receptor; and (3) whether those chemicals present in an environmental medium at a particular concentration will accumulate within a receptor at a level presumed to cause some significant adverse health effect.

It should be noted that all of the following equations have been described elsewhere.<sup>1,2,3</sup> They are reproduced in the current document, primarily for convenience, however, in some instances have been modified to remain consistent with specific rule language.

**A. Calculation of intake via inhalation:**

Of major importance in developing generic numerical standards is the necessity to account for uptake by the receptor through all potential exposure pathways. Thus, uptake via the inhalation pathway must account for exposure to volatile chemicals presented in vapor phase, as well as volatile, semi-volatile and non-volatile chemicals adhering to small soil particles. In order to calculate exposure to vapor phase chemicals, an apparent diffusivity value must first be calculated as presented in Equation (1), below.

1. Calculation of Apparent Diffusivities( $D_A$ )<sup>3</sup>:

$$D_A = \frac{(\theta_a^{10/3} \times D_i \times H') + (\theta_w^{10/3} \times D_w) / n^2}{\rho_b K_d + \theta_w + \theta_a H'} \quad (1)$$

Where:

$$\begin{aligned} D_A &= \text{Apparent diffusivity (cm}^2\text{/s)} \\ \theta_a &= \text{Air-filled soil porosity } (L_{\text{air}}/L_{\text{soil}})(0.28)^3 \end{aligned}$$

$D_i$	=	Diffusivity in air ( $\text{cm}^2/\text{s}$ )(chemical specific)
$H'$	=	Henry's Law Constant (dimensionless)(chemical specific)
$\theta_w$	=	Water-filled soil porosity ( $L_{\text{water}}/L_{\text{soil}}$ )(0.15) <sup>3</sup>
$D_w$	=	Diffusivity in water ( $\text{cm}^2/\text{s}$ )(chemical specific)
$n$	=	Total soil porosity ( $L_{\text{pore}}/L_{\text{soil}}$ )(0.43) <sup>3</sup>
$\rho_b$	=	Dry soil bulk density ( $\text{g}/\text{cm}^3$ )(1.5) <sup>3</sup>
$K_d$	=	Soil to water partition coefficient ( $\text{cm}^3/\text{gm}$ )

Note that chemical-specific values for  $D_i$ ,  $H'$ , and  $D_w$ , as well as toxicity data used to calculate the generic numerical standards are listed in Table II. For other chemicals, values should be obtained from the U.S. EPA Soil Screening Guidance, Technical Background Document<sup>3</sup>, whenever possible. For chemicals not listed in this source, other sources (e.g. other U.S. EPA databases) may be used. Verification of acceptability should be confirmed, however, by consultation with an Ohio EPA Division of Emergency and Remedial Response representative.

Once a value for  $D_A$  has been calculated, a volatilization factor can be calculated as in Equation (2), below.

2. Calculation of Volatilization Factor (VF)<sup>3</sup>:

$$VF = \frac{Q}{C} \times \frac{(3.14 \times D_A \times T)^{1/2}}{(2 \times \rho_b \times D_A)} \times 10^{-4} \quad (2)$$

Where:

VF	=	Volatilization Factor ( $\text{m}^3/\text{kg}$ )
Q/C	=	Inverse of the mean concentration at center of square source ( $\text{g}/\text{m}^2\text{-s}$ per $\text{kg}/\text{m}^3$ )(83.22, assuming a 0.5 acre area and Cleveland, Ohio climatic constants) <sup>3</sup>
$D_A$	=	Apparent diffusivity ( $\text{cm}^2/\text{s}$ )(from Equation 1)
T	=	Exposure Interval ( $9.5 \times 10^8$ sec) <sup>3</sup>
$\rho_b$	=	Dry soil bulk density ( $\text{g}/\text{cm}^3$ )(1.5) <sup>3</sup>

In addition to calculation of intake of volatiles by application of VF, the inhalation pathway must also account for inhalation of chemicals adhering to particulates. This aspect is addressed by determining a Particulate Emission Factor (PEF), which is calculated in Equation (3).

3. Calculation of Particulate Emission Factor (PEF)<sup>3</sup>:

$$PEF = \frac{Q}{C} \times \frac{3600}{0.036 \times (1 - V) \times (U_m \div U_t)^3 \times F_x} \quad (3)$$

Where:

- PEF = Particulate Emission Factor (m<sup>3</sup>/kg)
- Q/C = Inverse of the mean concentration at center of square source (g/m<sup>2</sup>-s per kg/m<sup>3</sup>)(83.22, assuming a 0.5 acre area and Cleveland, Ohio climatic constants)<sup>3</sup>
- V = Fraction of vegetative cover (unitless)(0.5)<sup>3</sup>
- U<sub>m</sub> = Mean annual windspeed (m/s)(4.2, average Cleveland, Ohio wind speed)<sup>3</sup>
- U<sub>t</sub> = Equivalent threshold value of windspeed at 7m (m/s)(11.32)<sup>3</sup>
- F<sub>x</sub> = Function dependent on U<sub>m</sub>/U<sub>t</sub> (unitless)(0.194)<sup>3</sup>

Once PEF and VF have been calculated, a complete intake factor for the inhalation pathway can be calculated on a chemical-specific basis by application of Equation (4).

#### 4. Calculation of Intake Factor for Inhalation Pathway (IF<sub>INH</sub>):

$$IF_{INH} = \frac{IR \times EF \times ED \times ET \times FInh \times \left( \frac{1}{PEF} + \frac{1}{VF} \right)}{(BW \times AT)} \quad (4)$$

Where:

- IF<sub>INH</sub> = Inhalation-specific intake factor (kg/kg-day)
- IR = Inhalation rate (m<sup>3</sup>/hr)(specific to each exposure scenario)
- EF = Exposure frequency (days/year)(specific to each exposure scenario)
- ED = Exposure duration (years)(specific to each exposure scenario)
- ET = Exposure time (hours/day)(specific to each exposure scenario)
- FInh = Fractional inhalation intake from contaminated source (unitless)
- PEF = Particulate emission factor (m<sup>3</sup>/kg)(See Equation (3))
- VF = Volatilization factor (m<sup>3</sup>/kg)(See Equation (2))
- BW = Body weight (mass)(kg)(specific to each exposure scenario)
- AT = Averaging time (days)(specific to each exposure scenario for cancer or non-cancer endpoints)

Note that the values for all input terms included in  $IF_{INH}$ , other than PEF and VF, are specific for each exposure scenario (land use category or activity). In instances where a probabilistic approach is used to calculate generic standards for chemicals not listed in rule 3745-300-08 of the Ohio Administrative Code, distributions obtained from specific exposure scenario sections can be used as input distributions for these factors. When standards are calculated using a point value (deterministic) approach, individual point values for these terms can be obtained from Table III. Alternatively, property specific data may be used for these values either through direct use of distributions (probabilistically) or by use of point values representing upper bound (or, in some cases central tendency) values of property-specific data distributions.

Under all exposure scenarios, the  $F_{INH}$  term is set equivalent to the comparable  $FI$  term for the ingestion pathway ( $IF_{ORAL}$ ), discussed below. In the probabilistic calculations,  $F_{INH}$  is derived from a uniform distribution (0.01 - 1.00) for all exposure scenarios. When standards are calculated using exposure point values, all of the inhaled soil intake is assumed to be derived from a contaminated source and is, therefore, equal to 100 percent (1.0). Alternatively, property specific data reflecting upper bound point value estimates of property-specific conditions may be used in accordance with rule 3745-300-09 (D)(3)(b)(iv) of the Ohio Administrative Code.

## B. Calculation of intake via ingestion:

In addition to intake via inhalation, ingestion represents a major pathway by which chemicals in the soil gain access to the body of a receptor. Similarly, a single intake factor may be calculated for this pathway as follows:

$$IF_{ORAL} = \frac{(IR \times EF \times ED \times FI \times CF)}{(BW \times AT)} \quad (5)$$

Where:

- $IF_{ORAL}$  = Ingestion-specific intake factor (kg/kg-day)
- $IR$  = Soil ingestion rate (mg/day)(specific to each exposure scenario)
- $EF$  = Exposure frequency (days/year)(specific to each exposure scenario)
- $ED$  = Exposure duration (years)(specific to each exposure scenario)
- $ET$  = Exposure time (hours/day)(specific to each exposure scenario)
- $FI$  = Fractional ingestion intake from contaminated source (unitless)
- $CF$  = Conversion factor ( $10^{-6}$ kg/mg)
- $BW$  = Body weight (mass)(kg)(specific to each exposure scenario)
- $AT$  = Averaging time (days)(specific to each exposure scenario for cancer or non-cancer endpoints)

Values for all input terms included in  $IF_{ORAL}$  (except CF) are specific for each exposure scenario. In instances where a probabilistic approach is used to calculate generic standards for chemicals not listed in rule 3745-300-08 of the Ohio Administrative Code, distributions obtained from the appropriate exposure scenario distribution section can be used as input distributions for these factors. FI is derived from a uniform distribution (0.01 - 1.00) for all exposure scenarios. When standards are calculated using exposure point values, all of the ingested soil intake is assumed to be derived from a contaminated source and is, therefore, equal to 100 percent (1.0). Alternatively, property specific data reflecting upper bound point value estimates of property-specific conditions may be used in accordance with rule 3745-300-09 (D)(3)(b)(iv) of the Ohio Administrative Code.

### C. Calculation of intake via dermal exposure:

The final intake pathway to be considered is through dermal exposure. However, the dermal exposure pathway only needs to be quantitatively assessed for a subset of semi-volatile organic compounds and metals. No volatile organic compounds need to be quantitatively assessed. The determination of whether a chemical of concern needs to be assessed for the dermal exposure pathway is made using Figure I, the dermal exposure assessment decision making flow chart for soils. As for the inhalation and ingestion pathways, a single intake factor is calculated by the following equation:

$$IF_{DERM} = \frac{(SA \times EF \times ED \times AF \times ABS \times FDerm \times CF)}{(BW \times AT)} \quad (6)$$

Where:

- $IF_{DERM}$  = Dermal-specific intake factor (kg/kg-day)
- SA = Surface area of exposed skin (cm<sup>2</sup>) (specific to each exposure scenario)
- EF = Exposure frequency (days/year)(specific to each exposure scenario)
- ED = Exposure duration (years)(specific to each exposure scenario)
- AF = Soil to skin adherence factor (mg/cm<sup>2</sup>) (specific to each exposure scenario)
- ABS = Dermal absorption fraction from soil (Table 1, or, if available from chemical specific data)
- FC = Fractional dermal intake from contaminated source (unitless)
- CF = Conversion factor (10<sup>-6</sup>kg/mg)
- BW = Body weight (mass)(kg)(specific to each exposure scenario)
- AT = Averaging time (days)(specific to each exposure scenario for cancer or non-cancer endpoints)

Except for CF and ABS, values for all other input terms included in  $IF_{DERM}$  are specific for each exposure scenario. In instances where a probabilistic approach

is used to calculate generic standards for chemicals not listed in rule 3745-300-08 of the Ohio Administrative Code, distributions obtained from specific exposure scenario sections can be used as input distributions for these factors. When standards are calculated using a point value approach, point values for these terms can be obtained from Table III. As with the inhalation pathway, the FC adjustment is equivalent to FI for default calculations. When standards are calculated using exposure point values, all of the soil contacted is assumed to be derived from a contaminated source and is, therefore, equal to 100 percent (1.0). Alternatively, property specific data reflecting upper bound point value estimates of property-specific conditions may be used in accordance with rule 3745-300-09 (D)(3)(b)(iv) of the Ohio Administrative Code.

Values for the dermal absorption fraction (ABS) are obtained from Table I, or can be obtained on a chemical-specific basis if available from an appropriate source and approved by an Ohio EPA Division of Emergency and Remedial Response representative.

**Table I. Dermal Absorption Fraction from Soil**

Compound	Dermal Absorption Fraction (ABS)	Source
Acenaphthylene	0.13	Wester et al. (1990)
Acenaphthene	0.13	Wester et al. (1990)
Anthracene	0.13	Wester et al. (1990)
Arsenic	0.03	Wester et al. (1993a)
Benzo(a)anthracene	0.13	Wester et al. (1990)
Benzo(a)pyrene	0.13	Wester et al. (1990)
Benzo(b)fluoranthene	0.13	Wester et al. (1990)
Benzo(k)fluoranthene	0.13	Wester et al. (1990)
Benzo(g,h,i)perylene	0.13	Wester et al. (1990)
Cadmium	0.001	Wester et al. (1992a)
Chlordane	0.04	Wester et al. (1992b)
Chrysene	0.13	Wester et al. (1990)
2,4-Dichlorophenoxyacetic acid	0.05	Wester et al. (1996)
Dibenz(a,h)anthracene	0.13	Wester et al. (1990)
4,4'-DDT	0.03	Wester et al. (1990)
Fluorene	0.13	Wester et al. (1990)
Fluoranthene	0.13	Wester et al. (1990)
Indeno(1,2,3-cd)pyrene	0.13	Wester et al. (1990)
Lindane (gamma BHC)	0.04	Duff & Kissel (1996)
2-Methylnaphthalene	0.13	Wester et al. (1990)
Naphthalene	0.13	Wester et al. (1990)
PCBs	0.14	Wester et al. (1993b)
Pentachlorophenol	0.25	Wester et al. (1993b)
Phenanthrene	0.13	Wester et al. (1990)

Compound	Dermal Absorption Fraction (ABS)	Source
Pyrene	0.13	Wester et al. (1990)
TCDD and other dioxins -if soil organic content is >10%	0.03 0.001	USEPA (1992)

D. Calculation of generic numerical standard:

Once intake factors have been calculated, they are combined in the following formulas for cancer and noncancer endpoints, and compared to the appropriate chemical-specific toxicity value as indicated:

1. Calculation of cleanup standard for **non-carcinogenic** endpoint:

$$TC = \frac{HQ}{\left(\frac{IF_{ORAL}}{RfD_{ORAL}}\right) + \left(\frac{IF_{DERM}}{RfD_{DERM}}\right) + \left(\frac{IF_{INH}}{RfD_{INH}}\right)} \quad (7)$$

Where:

- TC = Target cleanup concentration (mg/kg)
- HQ = Target hazard quotient (HQ=1)
- IF<sub>ORAL</sub> = Oral intake factor (Calculated as in Equation (5))
- IF<sub>DERM</sub> = Dermal intake factor (Calculated as in Equation (6))
- IF<sub>INH</sub> = Inhalation intake factor (Calculated as in Equation (4))
- RfD<sub>ORAL</sub> = Oral reference dose (Chemical specific)
- RfD<sub>DERM</sub> = Dermal reference dose (Chemical specific)
- RfD<sub>INH</sub> = Inhalation reference dose (Chemical specific)

2. Calculation of cleanup standard for **carcinogenic** endpoint:

$$TC = \frac{Target\ Risk}{[(IF_{ORAL} \times SF_{ORAL}) + (IF_{DERM} \times SF_{DERM}) + (IF_{INH} \times SF_{INH})]} \quad (8)$$

Where:

- TC = Target cleanup concentration (mg/kg)
- Target Risk = Target excess cancer rate (10<sup>-5</sup>)
- IF<sub>ORAL</sub> = Oral intake factor (Calculated as in Equation (5))
- IF<sub>DERM</sub> = Dermal intake factor (Calculated as in Equation (6))
- IF<sub>INH</sub> = Inhalation intake factor (Calculated as in Equation (4))

SF <sub>ORAL</sub>	=	Oral slope factor (Chemical specific)
SF <sub>DERM</sub>	=	Dermal slope factor (Chemical specific)
SF <sub>INH</sub>	=	Inhalation slope factor (Chemical specific)

The cleanup standards reflect cumulative effects of multiple exposure pathways. If warranted by property-specific conditions such as engineering controls, specific pathways may be eliminated. In addition to accounting for cumulative effects through multiple intake pathways, the cumulative effects of multiple contaminants must be considered. To address this concern, adjustments are made to individual TC values, such that the Total Hazard Index for non-cancer endpoints does not exceed 1, or the Target Risk Goal for carcinogenic endpoints does not exceed the appropriate level indicated in rules 3745-300-08 and 3745-300-09 of the Ohio Administrative Code. In the case of noncarcinogens, grouping of contaminants on the basis of their target organs and mechanism of action may be appropriate and result in the derivation of multiple hazard indices.

## II. Calculation of Generic Standards for unrestricted potable use ground water:

As with the generic direct-contact soil standards, the risk-derived generic unrestricted potable use ground water standards listed in Table VII of rule 3745-300-08 of the Ohio Administrative Code were developed using probabilistic simulations. Note that the generic unrestricted potable use standards in Table VI of rule 3745-300-08 of the Ohio Administrative Code are based on MCLs or other established regulatory criteria and therefore were not calculated using probabilistic simulations. As was the case for the direct-contact soil standards, chemicals that do not have a potable use standard listed in Tables VI or VII of rule 3745-300-08 of the Ohio Administrative Code may have a standard derived using either a point value (deterministic) analysis or through probabilistic simulations. Both methods of standard derivation are supported by a series of mathematical models which attempt to account for the uptake of chemicals from all exposure pathways by integrating intake terms for each of the pathways. Equations for each pathway are listed as follows:

### A. Calculation of intake via inhalation:

Intake for the inhalation pathway uses a single volatilization constant as described by Andelman<sup>5</sup> and applied originally to a whole house exposure scenario<sup>2</sup>. The model has been modified for the shower by applying an exposure time term to account only for time in the shower as follows:

$$IF_{INH} = \frac{(ED \times IR \times EF \times ET \times K \times CF_2)}{(BW \times AT)} \quad (9)$$

Where:

- $IF_{INH}$  = Inhalation-specific intake (L/kg-day)
- $ED$  = Exposure duration (years)(specific to child or adult receptor)
- $IR$  = Inhalation rate in shower ( $m^3/hr$ )(specific to child or adult receptor)
- $EF$  = Exposure frequency (days/year)
- $ET$  = Exposure time (hours/day)(0.2)
- $K$  = Volatilization constant (unitless)( $1.85 \times 10^{-3}$ )<sup>5</sup>
- $CF_2$  = Conversion factor ( $1 \times 10^3 L/m^3$ )<sup>2</sup>
- $BW$  = Body weight (mass)(kg)
- $AT$  = Averaging time (days)(specific to child or adult receptor for cancer or non-cancer endpoints)

B. Calculation of intake via ingestion:

Unlike intake through the inhalation pathway, which models only time spent in the shower, the intake term for ingestion accounts for the entire water consumption by the receptor, as indicated in the following equation:

$$IF_{ORAL} = \frac{(IR \times ED \times EF)}{(BW \times AT)} \quad (10)$$

Where:

- $IF_{ORAL}$  = Ingestion-specific intake factor (L/kg-day)
- $IR$  = Water ingestion rate(L/day)(specific to child or adult receptor)
- $ED$  = Exposure duration (years)(specific to child or adult receptor)
- $EF$  = Exposure frequency (days/year)
- $BW$  = Body weight (mass)(kg)(specific to child or adult receptor)
- $AT$  = Averaging time (days)(specific to child or adult receptor for cancer or non-cancer endpoints)

C. Calculation of intake via dermal exposure:

Like exposure through the inhalation pathway, dermal exposure to chemicals in groundwater are modeled only for time spent in the shower, as indicated in the following equation:

$$IF_{DERM} = \frac{(SA \times EF \times ED \times ET \times CF \times PC)}{(BW \times AT)} \quad (11)$$

Where:

IF <sub>DERM</sub>	=	Dermal-specific intake factor (L/kg-day)
SA	=	Surface area (cm <sup>2</sup> )(specific to child or adult receptor)
EF	=	Exposure frequency (days/year)
ED	=	Exposure duration (years)(specific to child or adult receptor)
ET	=	Exposure time (hours/day)(0.2) <sup>1</sup>
CF	=	Conversion factor (1x10 <sup>-3</sup> L/cm <sup>3</sup> )
PC	=	Permeability constant (cm/hr)(chemical specific)(specific to child or adult receptor)
BW	=	Body weight (mass)(kg)(specific to child or adult receptor)
AT	=	Averaging time (days)(specific to child or adult receptor for cancer or non-cancer endpoints)

#### D. Calculation of generic standards:

Once intake factors have been calculated, they are combined in the following formulas for cancer and noncancer endpoints, and compared to the appropriate chemical-specific toxicity value as indicated:

##### 1. Calculation of cleanup standard for non-carcinogenic endpoint:

$$TC = \left[ \frac{HQ}{\left( \frac{IF_{ORAL}}{RfD_{ORAL}} \right) + \left( \frac{IF_{DERM}}{RfD_{DERM}} \right) + \left( \frac{IF_{INH}}{RfD_{INH}} \right)} \right] \times 1000 \quad (12)$$

Where:

TC	=	Target cleanup concentration (ug/L)
HQ	=	Target hazard quotient (HQ=1)
IF <sub>ORAL</sub>	=	Oral intake factor (Calculated as in Equation (5))
IF <sub>DERM</sub>	=	Dermal intake factor (Calculated as in Equation (6))
IF <sub>INH</sub>	=	Inhalation intake factor (Calculated as in Equation (4))
RfD <sub>ORAL</sub>	=	Oral reference dose (Chemical specific)
RfD <sub>DERM</sub>	=	Dermal reference dose (Chemical specific)
RfD <sub>INH</sub>	=	Inhalation reference dose (Chemical specific)

##### 2. Calculation of cleanup standard for carcinogenic endpoint:

$$TC = \left[ \frac{Target\ Risk}{\left[ (IF_{ORAL} \times SF_{ORAL}) + (IF_{DERM} \times SF_{DERM}) + (IF_{INH} \times SF_{INH}) \right]} \right] \times 1000 \quad (13)$$

Where:

TC	=	Target cleanup concentration (ug/l)
Target Risk	=	Target excess cancer risk ( $10^{-5}$ - $10^{-4}$ , as appropriate)(see Rule 3745-300-09 of the Ohio Administrative Code)
IF <sub>ORAL</sub>	=	Oral intake factor (Calculated as in Equation (5))
IF <sub>DERM</sub>	=	Dermal intake factor (Calculated as in Equation (6))
IF <sub>INH</sub>	=	Inhalation intake factor (Calculated as in Equation (4))
SF <sub>ORAL</sub>	=	Oral slope factor (Chemical specific)
SF <sub>DERM</sub>	=	Dermal slope factor (Chemical specific)
SF <sub>INH</sub>	=	Inhalation slope factor (Chemical specific)

### III. Applicability of toxicity data for development of generic standards:

The development of reliable cleanup standards is dependent upon several sets of data describing 1. the physico-chemical characteristics for each chemical of concern; 2. the uptake of chemicals of concern from contaminated media, directly or indirectly, by a receptor; and 3. the capacity of a particular chemical to produce any carcinogenic or noncarcinogenic adverse health effects. With regard to obtaining toxicity values for the development of generic standards or use in a property-specific risk assessment, the following sources of toxicity information are used in order of decreasing preference:

#### A. Hierarchy of sources of pertinent toxicity information:

- (1) Integrated Risk Information System (IRIS). IRIS is considered to be the most reliable source of toxicity information. Since this source is updated on a monthly basis, the most current update of IRIS should be consulted.
- (2) Ohio EPA toxicity information. If the toxicity information required to be used in the development of the generic standards or for a property-specific risk assessment is not contained in IRIS, then the volunteer must consult with an Ohio EPA Division of Emergency and Remedial Response representative to determine the appropriate toxicity information for use. In general, the following hierarchy of additional sources is used by Ohio EPA to determine the most appropriate toxicity information.
  - (a) National Center for Environmental Assessment (NCEA) Provisional Values or Health Effects and Assessment Summary Tables (HEAST) toxicity information.
  - (b) Agency for Toxic Substances and Disease Registry (ATSDR) Toxicological Profiles.
  - (c) U.S. EPA Criteria Documents. Criteria documents include but are not limited to: drinking water criteria documents; drinking water health

advisory summaries; ambient water quality criteria documents; and air quality criteria documents.

B. Adjustment and extrapolation of toxicity values:

The toxicity values listed in IRIS and other sources for the inhalation pathway are most often presented as Reference Concentrations (RfC) or Air Unit Risk values for non-cancer and cancer endpoints, respectively. Therefore, in order to calculate cleanup standards for multiple pathways, these values must first be converted to Reference Dose (RfD) or Slope Factor (SF), using the following equations:

1. Conversion of RfC to RfD<sub>i</sub>:

$$RfD_i = \frac{RfC \times IR_{DAILY}}{BW} \quad (14)$$

Where:

- RfD<sub>i</sub> = Inhalation reference dose (mg/kg-day)
- RfC = Reference concentration (mg/m<sup>3</sup>)
- IR<sub>DAILY</sub> = Daily inhalation rate (m<sup>3</sup>/day)(IR<sub>DAILY</sub> = 20)<sup>1</sup>
- BW = Body weight (mass)(kg)(BW = 70 kg)<sup>1</sup>

2. Conversion of Air Unit Risk Factor to Inhalation Slope Factor:

$$SF_i = \left( \frac{Unit\ Risk}{IR_{DAILY}} \right) \times BW \times CF \quad (15)$$

Where:

- SF<sub>i</sub> = Inhalation slope factor (mg/kg-day)
- Air Unit Risk = Cancer unit risk ((μg/m<sup>3</sup>)<sup>-1</sup>)
- IR<sub>DAILY</sub> = Daily inhalation rate (m<sup>3</sup>/day)(IR<sub>DAILY</sub> = 20)<sup>1</sup>
- BW = Body weight (mass)(kg)(BW = 70 kg)<sup>1</sup>
- CF = Conversion factor (1000 μg/mg)

In addition, toxicity values are seldom available for all pathways, particularly for dermal absorption of chemicals from soil. In the absence of pathway specific toxicity values and specific information indicating that a particular pathway may not be applicable for a particular chemical constituent, extrapolated toxicity values may be used. It is important to note, however, that direct route-to-route extrapolation may not be appropriate, particularly when original data are based upon studies employing

administered rather than absorbed doses. In these instances, variability in chemical specific absorption efficiencies among different absorptive epithelial could result in invalid or highly uncertain toxicity values. Thus, appropriate route-to-route extrapolation should be confirmed by an Ohio EPA Division of Emergency and Remedial Response representative.

With regard to extrapolation of oral toxicity values to dermal pathway exposures, the extrapolated toxicity values are converted to absorbed dose values, as appropriate, since the dermal intake calculation takes into account dermal transfer efficiency (see Equation 5). Thus, any toxicity value not derived from absorbed dose data must be evaluated to determine whether adjustment by a gastrointestinal absorption factor is necessary. In the absence of chemical specific data, oral toxicity values derived from studies utilizing administered dose assume a default gastrointestinal absorption efficiency of 100% (oral absorption factor 1.0). The recommendation to assume 100% absorption is based on review of the literature where it has been found that organic chemicals are generally well absorbed (>50%) across the gastrointestinal tract. Although a wider range of absorption efficiencies have been reported for inorganics, the recommendation is to also assume 100% absorption for inorganics lacking a chemical-specific gastrointestinal absorption factor. Thus, for example, an oral reference dose derived from an administered dose critical study must be multiplied by a chemical-specific or default oral absorption factor (1.0), such that the reference dose is adjusted to account for the absorbed dose. Similarly, an oral slope factor derived from administered dose data must be divided by a chemical-specific or default oral absorption factor such that the slope factor is adjusted to account for the absorbed dose.

Oral slope factors ( $SF_o$ ) and reference doses ( $RfD_o$ ) are generally not extrapolated to assess inhaled exposures for compounds lacking inhalation values. However, in a limited number of cases, extrapolation from the oral to the inhalation toxicity criterion may be justified. For example, in the case where: 1) there are no inhalation toxicity criteria; 2) all of the exposure pathways involving oral toxicity information have been determined to be incomplete (e.g. direct contact with soils, potable use of ground water) per rule 3745-300-07 of the Ohio Administrative Code; and 3) the only complete exposure pathway is the exposure to volatiles present in indoor air due to vapor emissions from soil and/or ground water. An Ohio EPA Division of Emergency and Remedial Response representative should be consulted to confirm whether extrapolation of an oral toxicity value to an inhalation toxicity value is appropriate.

#### IV. Development of chemical-specific soil saturation levels:

It is recognized that in some instances, risk-based soil cleanup levels may exceed soil saturation levels. Under these conditions, it is possible that health hazards beyond chemical toxicity (e.g. flammability) may exist. Moreover, the ability to accurately predict receptor uptake levels from free phase chemical contamination based upon any

of the preceding mathematical models becomes highly problematic and has not been incorporated into these models.

Thus, for chemicals *other than* those specifically listed in Rule 3745-300-08 (B)(3)(a) (Petroleum Standards) of the Administrative Code, or for compounds that may be present in solid phase at ambient soil temperature, soil saturation levels may be calculated by the following formula<sup>3</sup>:

$$C_{SAT} = \frac{S}{\rho_b} (K_d \rho_b + \theta_w + H\theta_a) \quad (16)$$

Where:

- $C_{sat}$  = Soil saturation concentration (mg/kg)
- $S$  = Solubility in water (mg/L-water)(chemical specific)(see Table II)
- $\rho_b$  = Dry soil bulk density (kg/L)( $\rho_b = 1.5$ )<sup>3</sup>
- $K_d$  = Soil-water partition coefficient (L/kg)( $K_d = K_{oc} \times f_{oc}$  (see Table II) ( $f_{oc}$  = fraction organic carbon of soil ( $f_{oc} = 0.006$ )<sup>3</sup>)
- $\theta_w$  = Water-filled soil porosity ( $L_{water}/L_{soil}$ )( $\theta_w = 0.15$ )<sup>3</sup>
- $H'$  = Henry's Law Constant (dimensionless)(chemical specific)(see Table II)

#### V. Use of Monte Carlo simulation for probabilistic development of cleanup standards:

All of the preceding equations can be solved using single, deterministic, point values for each of the exposure parameters, to develop protective cleanup standards for soil, ground water, or any other exposure media and pathways as appropriate. In addition, by transformation of these equations to solve as a forward risk assessment, levels of risk to a receptor from chemicals present in the soil or groundwater at a known concentration may be calculated. Values for each of these input parameters have been recommended by U.S. EPA<sup>1-4,6,7</sup> or have been derived from primary sources by the Ohio EPA, incorporating a combination of central tendency (approximately 50<sup>th</sup> percentile) and upper bound (approximately 90<sup>th</sup>/95<sup>th</sup> percentile) exposure factors, and are listed in Table III.

Note that in instances where property-specific data are to be used as alternatives to these default input exposure parameters, it is required that they meet equivalent levels of certainty. Thus, in instances where an upper bound value is used for a default value, the corresponding property-specific value must be an upper bound (e.g. approximately 90<sup>th</sup>/95<sup>th</sup> percentile) value. Alternatively, when a default point value is derived from the central tendency value, a central tendency (e.g. approximately 50<sup>th</sup> percentile) value from the property-specific data is to be used.

In contrast to the use of single point values as input exposure factors, a probabilistic approach has been used to calculate the generic cleanup standards listed in Rule 3745-300-08 of the Ohio Administrative Code. This process involved performing iterative calculations in which the input terms were drawn from probability distributions of each of the appropriate exposure factors as listed in Section II of this document. By solving the above equations iteratively, populations of chemical concentrations which meet the appropriate cancer or non-cancer risk level ( $10^{-5}$  excess cancer risk or non-cancer hazard index of 1) under a wide range of possible exposures were developed. Values chosen for standards were selected from the resulting distributions at the 90<sup>th</sup> percentile level, such that in a forward risk assessment, 90% of these derived populations of concentrations would result in risk at the desired target risk levels. Alternatively, this could be described mathematically as only 10% of the derived population exceeding the target risk levels.

A similar probabilistic approach may be used in the calculation of standards derived through a property-specific risk assessment as described in Rule 3745-300-09 of the Ohio Administrative Code. Default distributions to be used in these analyses are listed in the specific exposure scenario sections in Section II. Alternatively, if property-specific conditions indicate the inapplicability of these default distributions and are supported by sufficient property-specific data, property-specific data may be used. Note, however, that the use of alternative distributions should be approved by an Ohio EPA Division of Emergency and Remedial Response representative.

Once appropriate exposure distributions, toxicological data, and physico-chemical data are obtained, the equations may be solved, iteratively, using one of several available Monte Carlo Simulation computer software packages. While many of the details for translating the intake equations to a computer model are specific to an individual software package, there are some minimal requirements regarding the use of probabilistic simulations. To maximize consistency and statistical validity, a minimum of 5000 iterations should be used. In addition, to facilitate sampling over the entire range of each input distribution, a Latin Hypercube Sampling protocol is preferred. Once the simulation has been completed and 90<sup>th</sup> percentile values are determined for use as a generic standard or in the property-specific risk assessment report, additional documentation must be provided for complete review. This documentation minimally includes:

1. Description of the input distributions if other than default:  
The description must include the shape (normal, lognormal, random, etc.), the range, and the mean and standard deviation (if available) of the probability distribution.
2. Summary statistics of sampled input distributions:  
Summary statistics must include the mean and standard deviation (if appropriate) and the selected range of values.

3. Descriptive statistics of concentration output data:  
Descriptive statistics must include mean, median, standard deviation, coefficient of variability, minimum and maximum value.
4. Cumulative percentile values for concentration output data:  
Cumulative percentile values expressed as mg/kg,  $\mu\text{g/L}$ , or other appropriate units of concentration for a given medium, should be presented for each percentile from 0-100 percent.

**Section II:**  
**Exposure Factor Value Derivations and Justifications**

<b>Land Use Category or Activity Exposure Scenario</b>	<b>Page Numbers</b>
Direct Contact Soils - Residential Adult Land Use	29-38
Direct Contact Soils - Residential Child Land Use	39-48
Direct Contact Soils - Commercial and Industrial Land Use	49-57
Direct Contact Soils - Construction and Excavation Activities	58-65
Unrestricted Potable Use Groundwater	66-73

DERIVATION AND JUSTIFICATION FOR THE DIRECT CONTACT SOIL EXPOSURE  
FACTOR VALUES FOR THE ADULT RECEPTOR IN THE RESIDENTIAL LAND USE  
CATEGORY

1. ( $ED_{\text{residential-adult}}$ ) Exposure Duration: This term is defined by a custom probability distribution based on the U.S. Census 2000 Supplementary Survey Summary Tables for the residency occupancy period data for Ohio.

Years at One Residence	Relative Probability
1	0.078
2 to 5	0.378
6 to 10	0.154
11 to 20	0.156
21 to 30	0.107
31 to 50	0.127

The selected distribution is based on data taking into account both rural and urban areas and both owner and renter occupied units.

2. ( $EF_{\text{residential-adult}}$ ) Exposure Frequency: This term is defined by a triangular distribution based on climate data and best professional judgement.

<i>Pathway:</i>	<i>Ingestion and Inhalation</i>	<i>Dermal Contact</i>
Maximum value:	365 days year <sup>-1</sup>	365 events year <sup>-1</sup>
Likeliest value:	330 days year <sup>-1</sup>	330 events year <sup>-1</sup>
Minimum value:	261 days year <sup>-1</sup>	261 events year <sup>-1</sup>

The maximum value assumes constant occupancy by a resident in an area of the state which does not have, on the average, one or more months of an average temperature below 32° F. Based on the soil surveys for Ohio counties, this is applicable to residences in parts of southern Ohio.

The likeliest value assumes that a resident will have minimal exposure to soil from outside during 4 weeks (28 days) of frozen ground and one week (7 days) of vacation.

The minimum value assumes a resident will have minimal exposure to soil from outside for 3 months (90 days), due to average temperatures below 32° F primarily in northern counties in Ohio or by residents who spend winters away. In addition, during the warmer weather months, it is assumed a resident is away from his home for 2 weeks (14 days) vacation.

3. ( $BW_{\text{residential-adult}}$ ) Body Weight: This term is defined by a normal distribution for an equal population of men and women from Finley, *et al.* (1994).

Arithmetic Mean:	71 kg
Standard Deviation:	15.9 kg
Minimum:	32 kg
Maximum:	115 kg

The minimum body weight was truncated at the lower end of the distribution at 32 kg accounting for elderly residents who may weigh less than other adults considered in the industrial worker scenario.

Reference: Finley, B., Proctor, D., Scott, P., Harrington, N., Paustenbach, D., and Price, P. (1994). Recommended distributions for exposure factors frequently used in health risk assessment. *Risk Analysis* 14(4):533-553. These values from Table II, for age > 18 years, both genders.

4. ( $IR_{\text{soil, residential-adult}}$ ) Soil Ingestion Rate: This term is defined by a uniform distribution based on the following key studies: Binder *et al.* (1986); Calabrese *et al.* (1989); Calabrese *et al.* (1990); Calabrese *et al.* (1997); Clausing *et al.* (1987), Davis *et al.* (1990); Hawley (1985); Stanek *et al.* (1997); Van Wijnen *et al.* (1990); and Walker and Griffin (1998).

Minimum:	10 mg day <sup>-1</sup>
Maximum:	200 mg day <sup>-1</sup>

The U.S. EPA standard default value for soil ingestion for adults in a residential setting of 100 mg day<sup>-1</sup> is derived as one-half of the 200 mg day<sup>-1</sup> default *average* soil ingestion rate for children. The key studies indicate a range of 10 mg day<sup>-1</sup> to 250 mg day<sup>-1</sup> for *average* soil ingestion rates for children (the upper percentile recommended value for children is 400 mg day<sup>-1</sup>, without including pica behavior), and adult daily soil ingestion range of 10 mg day<sup>-1</sup> to 200 mg day<sup>-1</sup>. Because of the high level of uncertainty associated with the limited data in the literature, upper bound values were not incorporated into the distribution, and rather a protective estimate of average values was used, including 200 mg/day which is a 90<sup>th</sup> percentile of the median of the best four trace elements reported by Stanek *et al.* (1997). The uniform distribution was selected as representative of adult soil ingestion rates for the range of residential activities

including regular indoor activities as well as working in attics and other dusty places, and outdoor activities such as gardening and yard work.

5. ( $FI_{\text{residential-adult}}$ ) Fraction Ingested of Soil that is Contaminated;  
 ( $FC_{\text{residential-adult}}$ ) Fraction of Dermally Contacted Soil that is Contaminated;  
 and ( $FInh_{\text{residential-adult}}$ ) Fraction of Air Inhaled Containing Volatiles and Particulates from a Contaminated Soil Source that is Contaminated: These terms represent the proportion of all soil at a Property, ingested, dermally contacted and inhaled, by the receptor population described, which is contaminated by the chemical of concern. In the simplest interpretation, they represent the proportion of the soil at a Property which is contaminated by a chemical of concern. They are expressed as the fraction of the surface area of the Property which is represented by the identified area(s) for that chemical of concern and assumes random activity and exposure patterns for a particular receptor at a Property. Thus exposure to soil concentrations of a chemical of concern, as represented by the exposure point concentration determined from the analytical results from the soil samples in the identified area(s), is assumed to occur only for those parts of the Property where the chemical of concern has been identified and quantified. On a property-specific basis, the terms can be uniquely constructed for each chemical of concern, or groups of chemicals of concern which are associated with a particular identified area(s), in accordance with paragraph (D)(3)(b)(iv)(A) of rule 3745-300-09 of the Ohio Administrative Code. If these terms are determined separately for each chemical of concern, the terms determined for each chemical of concern must be determined on the basis of all identified areas on a Property for which the chemical of concern has been identified and from which the exposure point concentration has been determined. Alternatively, the terms determined on a Property-specific basis may consider the spatial distribution of the chemical(s) of concern and the receptor activity patterns on a Property; the derivation of such property-specific  $FI_{\text{residential-adult}}$ ,  $FC_{\text{residential-adult}}$ , and  $FInh_{\text{residential-adult}}$  terms on the basis of receptor activity patterns and their relationship to the identified area(s) must be performed in accordance with paragraph (D)(3)(b)(iv)(B) of rule 3745-300-09 of the Ohio Administrative Code. For purposes of the generic numerical direct-contact soil standards, these terms have been defined by a uniform distribution:

Minimum: 0.01 (unitless)  
 Maximum: 1.00 (unitless)

A uniform distribution assumes equal probability of all combinations of contamination and activity patterns upon a property. For purposes of the generic numerical direct-contact soil standards, these terms have been defined by a uniform distribution from which, for each iteration, a value is selected for the  $FI_{\text{residential-adult}}$  term; the correlation between the Fraction Ingested, Fraction Dermally Contacted and Fraction Inhaled terms was accounted for by setting the value for the  $FC_{\text{residential-adult}}$  and  $FInh_{\text{residential-adult}}$  terms equal to the value selected from the  $FI_{\text{residential-adult}}$  distribution such that, for each iteration:

$$FI_{\text{residential-adult}} = FC_{\text{residential-adult}} = FInh_{\text{residential-adult}}$$

In the course of performing a Property-specific risk assessment, distributions may be developed for each of the  $FI_{\text{residential-adult}}$ ,  $FC_{\text{residential-adult}}$  and  $Flnh_{\text{residential-adult}}$  terms. In this case, the selection of a value from a distribution for the  $FI_{\text{residential-adult}}$  term may be correlated to the selection of a value from the distributions for the  $FC_{\text{residential-adult}}$  and  $Flnh_{\text{residential-adult}}$  terms on a Property-specific basis in accordance with paragraph (D)(3)(b)(iv) of Rule 3745-300-09 of the Ohio Administrative Code.

6. ( $SA_{\text{residential-adult}}$ ) Skin Surface Area Exposed: This term is defined as the product of the two distributions described as follows, Total Skin Surface Area and Fraction Skin Surface Area Exposed:

$$SA_{\text{residential-adult}} = SA_{\text{total, residential-adult}} \times fSA_{\text{exp, residential-adult}}$$

These two distributions are described as follows:

- 6a. ( $SA_{\text{total, residential-adult}}$ ) Total Skin Surface Area: This distribution is dependent upon the distribution for Body Weight ( $BW_{\text{residential-adult}}$ ) by means of a distribution of surface area to body weight ratios derived by Phillips *et al.* (1993), who observed a strong correlation between surface area and body weight. The total skin surface area for adults was calculated based on the following Equation:

$$SA_{\text{total, residential-adult}} (\text{cm}^2) = x \text{ cm}^2 \text{ kg}^{-1} \times BW_{\text{residential-adult}} (\text{kg})$$

where, based on a correlation coefficient between the surface area to body weight ratio and body weight,  $x$  is selected from a distribution of surface area to body weight ratios for male and female adults aged 18 years and older described as follows:

Minimum:	200 $\text{cm}^2 \text{ kg}^{-1}$
Mean:	284 $\text{cm}^2 \text{ kg}^{-1}$
Maximum:	351 $\text{cm}^2 \text{ kg}^{-1}$
Standard deviation:	28 $\text{cm}^2 \text{ kg}^{-1}$

The correlation coefficient of -0.841 for the relationship of adult surface area: body weight ratio to body weight was derived on the basis of personal communication with Phillips (1996).

Reference: Phillips, L.J., Fares, R.J., and Schweer, L.G. (1993). Distributions of total skin surface area to body weight ratios for use in dermal exposure assessments. *J. Expos. Anal. Environ. Epid.* 3:331-338.

Phillips, L.J. personal communication with Ohio EPA, 17 October 1996.

6b. ( $fSA_{exp_{residential-adult}}$ ) Fraction Skin Surface Area Exposed: This term is defined by a triangular distribution based upon assumptions about clothing associated with various residential activity and season scenarios and, consequently, the proportion of total skin surface area corresponding to the exposed body parts.

Maximum: 0.59  
Likeliest: 0.42  
Minimum: 0.17

The dermal contact pathway is an event-driven pathway, assuming that single or multiple contact events with soil per day result in an exposure to total dose. The quantification of daily exposure through the dermal contact pathway is therefore independent of the time spent in contact with the soil.

The minimum value assumes that a resident is wearing short-sleeved shirt and pants and that the hands, forearms, head and neck are exposed in the eight warm weather months per year, and that only the hands and head are exposed in the four cold weather months per year. The body part surface areas for the exposed areas for each weather period were added and a time-weighted average value for the year thus derived.

The likeliest value assumes that a resident is wearing short pants and short-sleeved shirt and that the head, neck, forearms, hands, legs and feet (allowing for bare feet or sandal shoes) are exposed in the eight warm weather months per year, and that only the head and hands are exposed in the four cold weather months per year. The body part surface areas for the exposed areas for each weather period were added and a time-weighted average value for the year thus derived.

The maximum value assumes that a resident is wearing short pants, and that the head, neck, arms, hands, one-half the trunk and legs and feet (allowing for bare feet or sandal shoes) are exposed in the eight warm weather months per year and that only the head and hands are exposed in the cold weather months per year. The body part surface areas for the exposed areas for each weather period were added and a time-weighted average value for the year thus derived.

Reference: U.S. EPA (1997). *Exposure Factors Handbook*. EPA/600/8-89/043.

7. ( $AF_{residential-adult}$ ) Soil Skin Adherence Factor: This term is defined by a triangular distribution based the data from a broad range of activities from the following key studies: Holmes *et al* (1999); Kissel *et al.* (1996); and Kissel *et al.* (1998).

Minimum: 0.06  $mg\ cm^{-2}$

Likeliest:	0.2	mg cm <sup>-2</sup>
Maximum:	0.3	mg cm <sup>-2</sup>

The minimum value represents an AF value for a range of activities associated with lower soil contact rates that an adult resident may engage in.

The likeliest value combines central tendency and upper bound weighted AFs for a variety of activities.

The maximum value combines upper bound weighted AFs with higher soil direct contact activities.

References: Holmes Jr., K.K., Shirai, J.H., Richter, K.Y., and Kissel, J.C. (1999). Field measurement of dermal soil loadings in occupational and recreational activities. *Environ. Res.* A80:148-157.

Kissel, J.C., Richter, K.Y. and Fenske, R.A. (1996). Field measurement of dermal soil loading attributable to various activities: implications for exposure assessment. *Risk Analysis* 16:115-125.

Kissel, J.C., Shirai, J.H., Richter, K.Y., and Fenske, R.A. (1998). Investigation of dermal contact with soil in controlled trials. *J. Soil Contam.* 7(6):737-752.

8. (IR<sub>inh residential-adult</sub>) Inhalation Rate: This term is defined by a triangular distribution based on key studies summarized in the U.S. EPA *Exposure Factors Handbook* (1997) Table 5-23

Minimum:	0.60 m <sup>3</sup> hour <sup>-1</sup>
Likeliest:	0.90 m <sup>3</sup> hour <sup>-1</sup>
Maximum:	1.10 m <sup>3</sup> hour <sup>-1</sup>

The selected distribution is based on the percentage of time that a resident spends at rest, and on sedentary, light, moderate, and heavy activities. The inhalation rate varies with the activity level.

The minimum value is based on the average of male and female adult average activity-specific inhalation rates assuming one-third of the time at resting rate (0.4 m<sup>3</sup> hour<sup>-1</sup>), one-third of the time at sedentary activities rate (0.5 m<sup>3</sup> hour<sup>-1</sup>), and one-third of the time at light activities rate (1.0 m<sup>3</sup> hour<sup>-1</sup>).

The likeliest value is based on the average of male and female adult average activity-specific inhalation rates assuming one-third of the time at resting rate, one-sixth of the

time at sedentary activities rate, one-fourth of the time at light activities rate and one-fourth of the time at moderate activities rate ( $1.6 \text{ m}^3 \text{ hour}^{-1}$ ).

The maximum value is based on the average of male and female adult average activity-specific inhalation rates, assuming one-third of the time at resting rate, one-twelfth of the time at sedentary rate, one-fourth of the time at light activities rate, one-fourth of the time at moderate activities rate and one-twelfth of the time at heavy activities rate ( $3.2 \text{ m}^3 \text{ hour}^{-1}$ ).

Reference: U.S. EPA. *Exposure Factors Handbook*. 1997. Office of Research and Development. Washington, D.C.

9. ( $ET_{inh}$  residential-adult) Exposure Time for Inhalation: This term is defined as a custom distribution.

50 percent probability: 16 hour day<sup>-1</sup>  
50 percent probability: 24 hour day<sup>-1</sup>

The distribution is based on the assumption that some residents would spend 8 hours a day at work thereby reducing residential exposure time to 16 hours whereas others may spend all their time at home.

10. (ABS) Absorption Factor. Chemical-specific. Refer to Table I in Section I.  
11. (AT) Averaging Time.

for Noncarcinogens:  $ncAT = ED \times 365 \text{ days year}^{-1}$

for Carcinogens (point value):  $cAT = 70 \text{ years} \times 365 \text{ days year}^{-1}$   
 $= 25550 \text{ days}$

U.S. EPA (1991). *Human Health Exposure Manual, Supplemental Guidance: Standard Default Exposure Factors*. OSWER Directive 9285.6-03.

12. (CF) Conversion Factor. Point value.

$CF = 1 \times 10^{-6} \text{ kg mg}^{-1}$

Reference: U.S. EPA (1989). *Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual, Part A*. EPA/540/1-89/002.

13. (VF) Volatilization Factor: This term is defined as a point value, which is calculated on a chemical-specific basis, according to the equation described in paragraph I.A.2 of Section I of this document. Calculation of the VF term requires chemical-specific values for:

$D_i$ : Diffusivity in air ( $\text{cm}^2 \text{s}^{-1}$ )  
 $H'$ : Dimensionless Henry's law constant  
 $D_w$ : Diffusivity in water ( $\text{cm}^2 \text{s}^{-1}$ )  
 $K_d$ : Soil-water partitioning coefficient ( $\text{cm}^3 \text{g}^{-1}$ )  
 $K_{oc}$ : Soil organic carbon-water partitioning coefficient ( $\text{cm}^3 \text{g}^{-1}$ )

as described by U.S. EPA (1996).

Reference: U.S. EPA (1996). *Soil Screening Guidance: Technical Background Document*. Section 2.4.2. Office of Solid Waste and Emergency Response. EPA/540/R-95/128. PB96-963502. May 1996. 168 pp. plus appendices.

14. (PEF) Particulate Emissions Factor: This term is defined as a point value calculated according to the methodology described in Section I of this document. It incorporates climate data from Cleveland, Ohio.

$$\text{PEF} = 1.68 \times 10^9 \text{ m}^3 \text{ kg}^{-1}$$

Calculation of this term on a Property-specific basis as described in the equation found in paragraph I.A.3 of Section I of this document and must be performed in accordance with paragraph (D)(3)(b)(iv)(A) of rule 3745-300-09 of the Ohio Administrative Code.

Reference: U.S. EPA (1996). *Soil Screening Guidance: Technical Background Document*. Section 2.4.5. Office of Solid Waste and Emergency Response. EPA/540/R-95/128. PB96-963502. May 1996. 168 pp. plus appendices.

DERIVATION AND JUSTIFICATION FOR THE DIRECT CONTACT SOIL EXPOSURE FACTORS FOR THE CHILD RECEPTOR IN THE RESIDENTIAL LAND USE CATEGORY

1. ( $ED_{\text{residential-child}}$ ) Exposure Duration: This term is defined by a custom probability distribution based on U.S. Census 2000 Supplementary Survey Summary Tables for the residency occupancy period data for Ohio.

Years at One Residence	Relative Probability
1	0.078
2 to 5	0.378
6	0.544

The adult distribution was used for the child receptor except that all the probabilities above 6 years were truncated and added to the sixth year. If the simulation picks up a number higher than six years, then this distribution assures that a maximum of 6 years are accounted for a child.

2. ( $EF_{\text{residential-child}}$ ) Exposure Frequency: This term is defined by a triangular distribution based on climate data and best professional judgement.

<i>Pathway:</i>	<i>Ingestion and Inhalation</i>	<i>Dermal Contact</i>
Maximum value:	365 days year <sup>-1</sup>	365 events year <sup>-1</sup>
Likeliest value:	330 days year <sup>-1</sup>	330 events year <sup>-1</sup>
Minimum value:	261 days year <sup>-1</sup>	261 events year <sup>-1</sup>

The maximum value assumes constant occupancy by a child resident in an area of the state which does not have, on the average, one or more months of an average temperature below 32°F. Based on the soil surveys for Ohio counties, this is applicable to residences in southern Ohio.

The likeliest value assumes that a child will have minimal exposure to soil from the property during 4 weeks (28 days) of frozen ground and one week (7 days) of vacation.

The minimum value assumes a child will have minimal exposure to soil from outside during 3 months (90 days) due to average temperatures below 32°F, primarily in northern Ohio counties, or due to children that spend time away from one residence to live at another residence based on divorce/joint custody cases. In addition, during the warmer weather months, it is assumed a child is away from the residence for 2 weeks (14 days) vacation.

3. ( $BW_{\text{residential-child}}$ ) Body Weight: This term is defined as a normal distribution for an equal population of male and female children from Smith (1994).

Mean:	15 kg
Standard deviation:	1.95 kg

Reference: Smith, R.L. (1994). Use of Monte Carlo simulation for human exposure assessment at a Superfund site. *Risk Analysis* 14:433-439.

4. ( $IR_{\text{soil residential-child}}$ ) Soil Ingestion Rate: Custom distribution based on the following key studies for children: Binder et al. (1986); Bruhn and Panghorn (1971); Calabrese et al. (1989); Calabrese et al. (1997); Clausing et al. (1987); Danford (1982); Davis et al. (1990); Van Wijnen et al. (1990); and Walker and Griffin (1998).

<u>Range</u>	<u>Relative Probability</u>
10 to 100 mg per day	0.2
101 to 250 mg per day	0.6
251 to 592 mg per day	0.2

Soil ingestion studies cited for the determination of the soil ingestion rate are based on studies in which the subjects (children) were generally outside for limited time periods for play, etc. The studies measured daily soil ingestion rates with the children being outside for normal activity patterns, including play, but not for the whole day or for extended periods of the day. Therefore, corrections for indoor *versus* outdoor time are not appropriate, and no hourly adjustments are made. In addition, children tend to exhibit periods of intensive mouthing behavior which results in soil and dust being transferred from their hands and play objects to their mouths. Child soil ingestion is considered here to be more of an event or periodic occurrence and less a continual process.

10 to 100 mg day<sup>-1</sup>: relative probability 0.2. This lower range accounts for the lower estimates of soil ingestion reported in the key studies.

101 to 250 mg day<sup>-1</sup>: relative probability 0.6. This range is based on an analysis of the mean soil ingestion estimates for children summarized in the key studies. These key studies vary in survey designs and study populations and several account for food and non-food sources of trace elements. Several studies adjust the soil ingestion rates to

account for household dust. The mean soil ingestion estimates from these key studies are relatively consistent and generally fall within this range.

251 to 590 mg day<sup>-1</sup>: relative probability 0.2. This upper range accounts for the upper percentile values reported in the key studies. It also attempts to account for the prevalence of soil pica behavior. Bruhn and Pangborn (1971) estimated that the prevalence of pica for "dirt" was approximately 19 percent for children. A number of articles in the scientific literature report the incidence of pica for substances other than soil itself and include sand, clay, paint, paper, etc. These studies report pica incidence rates between 10 and 60 percent (Lourie *et al.* 1963; Vermeer and Frate 1979; Danford 1982; Kaplan and Sadock 1985; Sayetta 1986). The Calabrese *et al.* (1989) study included one pica child with an average soil ingestion rate of 5 to 7 g day<sup>-1</sup>. However, significant pica behavior generally occurs for a short time period and not for the entire duration of exposure.

The upper range for the child soil ingestion rate was derived by defining a pica period (4 years duration) and a normal period (2 years duration) for the upper end of the population distribution. Pica soil ingestion was calculated as a soil ingestion rate of 1000 mg day<sup>-1</sup> for 4 days week<sup>-1</sup> and 500 mg day<sup>-1</sup> for 3 days week<sup>-1</sup>. The normal period ingestion rate was set uniformly at 200 mg day<sup>-1</sup>. The derivation can be mathematically expressed as follows:

$$\begin{aligned}
 & 1000 \text{ mg day}^{-1} \times (4 \text{ day} / 7 \text{ day}) \times (4 \text{ year} / 6 \text{ year}) = 381 \\
 + & 500 \text{ mg day}^{-1} \times (3 \text{ day} / 7 \text{ day}) \times (4 \text{ year} / 6 \text{ year}) = 143 \\
 + & \underline{200 \text{ mg day}^{-1}} \times \underline{(7 \text{ day} / 7 \text{ day})} \times \underline{(2 \text{ year} / 6 \text{ year})} = \underline{67} \\
 & \hspace{15em} 591 \text{ mg day}^{-1}
 \end{aligned}$$

5. ( $FI_{\text{residential-child}}$ ) Fraction Ingested of Soil that is Contaminated;  
( $FC_{\text{residential-child}}$ ) Fraction of Dermal Contacted Soil that is Contaminated;  
and ( $FI_{\text{inh-residential-child}}$ ) Fraction of Air Inhaled Containing Volatiles and Particulates from a Contaminated Soil Source that is Contaminated: These terms represent the proportion of all soil at a Property, ingested, dermally contacted and inhaled, by the receptor population described, which is contaminated by the chemical of concern. In the simplest interpretation, they represent the proportion of the soil at a Property which is contaminated by a chemical of concern. They are expressed as the fraction of the surface area of the Property which is represented by the identified area(s) for that chemical of concern and assumes random activity and exposure patterns for a particular receptor at a Property. Thus exposure to soil concentrations of a chemical

of concern, as represented by the exposure point concentration determined from the analytical results from the soil samples in the identified area(s), is assumed to occur only for those parts of the Property where the chemical of concern has been identified and quantified. On a property-specific basis, the terms can be uniquely constructed for each chemical of concern, or groups of chemicals of concern which are associated with a particular identified area(s), in accordance with paragraph (D)(3)(b)(iv)(A) of rule 3745-300-09 of the Ohio Administrative Code. If these terms are determined separately for each chemical of concern, the terms determined for each chemical of concern must be determined on the basis of all identified areas on a Property for which the chemical of concern has been identified and from which the exposure point concentration has been determined. Alternatively, the terms determined on a Property-specific basis may consider the spatial distribution of the chemical(s) of concern and the receptor activity patterns on a Property; the derivation of such property-specific  $FI_{\text{residential-child}}$ ,  $FC_{\text{residential-child}}$ , and  $FInh_{\text{residential-child}}$  terms on the basis of receptor activity patterns and their relationship to the identified area(s) must be performed in accordance with paragraph (D)(3)(b)(iv)(B) of rule 3745-300-09 of the Ohio Administrative Code. For purposes of the generic numerical direct-contact soil standards, these terms have been defined by a uniform distribution:

Minimum: 0.01 (unitless)  
 Maximum: 1.00 (unitless)

A uniform distribution assumes equal probability of all combinations of contamination and activity patterns upon a property. For purposes of the generic numerical direct-contact soil standards, these terms have been defined by a uniform distribution from which, for each iteration, a value is selected for the  $FI_{\text{residential-child}}$  term; the correlation between the Fraction Ingested, Fraction Dermally Contacted and Fraction Inhaled terms was accounted for by setting the value for the  $FC_{\text{residential-child}}$  and  $FInh_{\text{residential-child}}$  terms equal to the value selected from the  $FI_{\text{residential-child}}$  distribution such that, for each iteration:

$$FI_{\text{residential-child}} = FC_{\text{residential-child}} = FInh_{\text{residential-child}}$$

In the course of performing a Property-specific risk assessment, distributions may be developed for each of the  $FI_{\text{residential-child}}$ ,  $FC_{\text{residential-child}}$  and  $FInh_{\text{residential-adult}}$  terms. In this case, the selection of a value from a distribution for the  $FI_{\text{residential-child}}$  term may be correlated to the selection of a value from the distributions for the  $FC_{\text{residential-child}}$  and  $FInh_{\text{residential-child}}$  terms on a Property-specific basis in accordance with paragraph (D)(3)(b)(iv) of Rule 3745-300-09 of the Ohio Administrative Code.

6. ( $SA_{\text{residential-child}}$ ) Skin Surface Area Exposed: This term is defined as the product of the two distributions described as follows, Total Skin Surface Area and Fraction Skin Surface Area Exposed:

$$SA_{\text{residential-child}} = SA_{\text{total, residential-child}} \times fSA_{\text{exp, residential-child}}$$

These two distributions are described as follows:

- 6a. ( $SA_{total, residential-child}$ ) Total Skin Surface Area: This distribution is dependent upon the distribution for Body Weight ( $BW_{residential-child}$ ) by means of a distribution of surface area to body weight ratios derived by Phillips *et al.* (1993), who observed a strong correlation between surface area and body weight. The total skin surface area for children was calculated based on the following Equation:

$$SA_{total, residential-child} (cm^2) = x \text{ cm}^2 \text{ kg}^{-1} \times BW_{residential-child} (kg)$$

where, based on a correlation coefficient between the surface area to body weight ratio and body weight,  $x$  is selected from a distribution of surface area to body weight ratios for male and female children, aged 2.1 to 17.9 years of age.

Minimum:	268 cm <sup>2</sup> kg <sup>-1</sup>
Mean:	423 cm <sup>2</sup> kg <sup>-1</sup>
Maximum:	670 cm <sup>2</sup> kg <sup>-1</sup>
Standard deviation:	76 cm <sup>2</sup> kg <sup>-1</sup>

The correlation coefficient of -0.819 for the relationship of child surface area: body weight ratio to body weight was derived on the basis of personal communication with Phillips (1996).

Reference: Phillips, L.J., Fares, R.J., and Schweer, L.G. (1993). Distributions of total skin surface area to body weight ratios for use in dermal exposure assessments. *J. Expos. Anal. Environ. Epid.* 3:331-338.

Phillips, L.J. personal communication with Ohio EPA, 17 October 1996.

- 6b. ( $fSA_{exp, residential-child}$ ) Fraction Skin Surface Area Exposed: This term is defined by a triangular distribution based upon assumptions about clothing associated with various residential activity and season scenarios and, consequently, the proportion of total skin surface area corresponding to the exposed body parts.

Minimum:	0.24
Likeliest:	0.46
Maximum:	0.62

The dermal contact pathway is an event-driven pathway, assuming that single or multiple contact events with soil per day result in an exposure to total dose. The

quantification of daily exposure through the dermal contact pathway is therefore independent of the time spent in contact with the soil.

All values were derived from data in U.S. EPA (1989). The values for the proportion of body part surface area were determined from the average of the sum of the mean values for the age cohorts <1, 1<2, 2<3, 3<4, 4<5 and, to represent a value for 5<6 for which no data existed,  $\{(4<5 + 6<7) / 2\}$ . The values in this distribution were calculated as a time-weighted average of the exposed surface area in four cold weather months and the skin surface area exposed during eight warm weather months. The minimum, likeliest and maximum fraction skin surface area exposed for the cold weather months was determined from the same exposure scenario, and assumed a child with only head and hands exposed. The fraction skin surface area exposed for the eight warm weather months were defined as follows:

The minimum value assumes that a child resident is wearing short-sleeved shirt and pants and that the hands, forearms, head and neck are exposed during the warm weather months.

The likeliest value assumes that a child resident is wearing short-sleeved shirt and short pants and that hands, forearms, head, neck, legs and feet (allowing for bare feet or sandal shoes) are exposed during the warm weather months.

The maximum value assumes that a child resident is wearing short pants and that the hands, head, neck, arms, legs and one-half the trunk are exposed during the warm weather months.

Reference: U.S. EPA (1997). *Exposure Factors Handbook*. EPA/600/8-89/043.

7. ( $AF_{\text{residential-child}}$ ) Soil Skin Adherence Factor: This term is defined by a triangular distribution based on data from a broad range of activities from the following key studies: Holmes *et al* (1999); Kissel *et al*. (1996); and Kissel *et al*. (1998).

Minimum:	0.06	mg cm <sup>-2</sup>
Likeliest:	0.3	mg cm <sup>-2</sup>
Maximum:	0.4	mg cm <sup>-2</sup>

The minimum value combines central tendency weighted AFs for children primarily indoors and in a day care setting, as well as upper bound AFs for children in a day care setting.

The likeliest value combines upper bound weighted AFs for children in a day care setting and also incorporates periodic exposures to wet soil.

The maximum value combines upper bound weighted AFs for children playing in dry soil and also incorporates periodic exposures to wet soil.

References: Holmes Jr., K.K., Shirai, J.H., Richter, K.Y., and Kissel, J.C. (1999). Field measurement of dermal soil loadings in occupational and recreational activities. *Environ. Res.* A80:148-157.

Kissel, J.C., Richter, K.Y. and Fenske, R.A. (1996). Field measurement of dermal soil loading attributable to various activities: implications for exposure assessment. *Risk Analysis* 16:115-125.

Kissel, J.C., Shirai, J.H., Richter, K.Y., and Fenske, R.A. (1998). Investigation of dermal contact with soil in controlled trials. *J. Soil Contam.* 7(6):737-752.

8. ( $IR_{inh, \text{residential-child}}$ ) Inhalation Rate: This term is defined by a triangular distribution based on key studies summarized in the U.S. EPA *Exposure Factors Handbook* (1997).

Minimum: 0.57 m<sup>3</sup> hour<sup>-1</sup>  
Likeliest: 0.66 m<sup>3</sup> hour<sup>-1</sup>  
Maximum: 0.73 m<sup>3</sup> hour<sup>-1</sup>

The selected distribution is based on the percentage of time that a child resident spends at rest, and on light, moderate, and heavy activities. The inhalation rate varies with the activity level.

The minimum value derived from the inhalation rates for young children (both genders) assumes based on a 24 hour day, twelve hours at rest (0.4 m<sup>3</sup> hour<sup>-1</sup>), ten hours at light activities (0.65 m<sup>3</sup> hour<sup>-1</sup>), and two hours at moderate activities (1.2 m<sup>3</sup> hour<sup>-1</sup>).

The likeliest value is derived from the inhalation rates for young children (both genders) and assumes twelve hours at rest, six hours at light activities, and six hours at moderate activities (1.6 m<sup>3</sup> hour<sup>-1</sup>).

The maximum value is derived from the inhalation rates of young children and assumes ten hours at rest, six hours at light activities, eight hours at moderate activities.

Reference: U.S. EPA. *Exposure Factors Handbook*. 1997. Office of Research and Development. Washington, D.C.

9. ( $ET_{inh, \text{residential-child}}$ ) Exposure Time Inhalation: This term is defined as a custom distribution based upon best professional judgement.

25 percent probability - 16 hour day<sup>-1</sup>

75 percent probability - 24 hour day<sup>-1</sup>

The distribution is based on the assumption that some children may spend 8 hours a day away from home at a day care facility or school reducing residential exposure time to 16 hours whereas others may spend all their time at home.

10. (ABS) Absorption Factor. Chemical-specific. Refer to Table I in Section I.
11. (AT) Averaging Time.

for Noncarcinogens:  $ncAT = ED \times 365 \text{ days year}^{-1}$

for Carcinogens (point value):  $cAT = 70 \text{ years} \times 365 \text{ days year}^{-1}$   
 $= 25550 \text{ days}$

U.S. EPA (1991). *Human Health Exposure Manual, Supplemental Guidance: Standard Default Exposure Factors*. OSWER Directive 9285.6-03.

12. (CF) Conversion Factor: This term is defined as a point value.

$$CF = 1 \times 10^{-6} \text{ kg mg}^{-1}$$

Reference: U.S. EPA (1989). *Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual, Part A*. Exhibit 6-14. EPA/540/1-89/002.

13. (VF) Volatilization Factor: This term is defined as a point value, which is calculated on a chemical-specific basis, according to the equation described in paragraph I.A.2 of Section I of this document. Calculation of the VF term requires chemical-specific values for:

$D_i$ : Diffusivity in air ( $\text{cm}^2 \text{ s}^{-1}$ )  
 $H'$ : Dimensionless Henry's law constant  
 $D_w$ : Diffusivity in water ( $\text{cm}^2 \text{ s}^{-1}$ )  
 $K_d$ : Soil-water partitioning coefficient ( $\text{cm}^3 \text{ g}^{-1}$ )  
 $K_{oc}$ : Soil organic carbon-water partitioning coefficient ( $\text{cm}^3 \text{ g}^{-1}$ )

as described by U.S. EPA (1996) cited below.

Reference: U.S. EPA (1996). *Soil Screening Guidance: Technical Background Document*. Section 2.4.2. Office of Solid Waste and Emergency Response. EPA/540/R-95/128. PB96-963502. May 1996. 168 pp. plus appendices.

14. (PEF) Particulate Emissions Factor: This term is defined as a point value calculated according to the methodology described in Section I of this document. It incorporates climate data from Cleveland, Ohio.

$$\text{PEF} = 1.68 \times 10^9 \text{ m}^3 \text{ kg}^{-1}$$

Calculation of this term on a Property-specific basis as described in the equation found in paragraph I.A.3 of Section I of this document must be performed in accordance with paragraph (D)(3)(b)(iv)(A) of rule 3745-300-09 of the Ohio Administrative Code.

Reference: U.S. EPA (1996). *Soil Screening Guidance: Technical Background Document*. Section 2.4.5. Office of Solid Waste and Emergency Response. EPA/540/R-95/128. PB96-963502. May 1996. 168 pp. plus appendices.

DERIVATION AND JUSTIFICATION FOR THE DIRECT CONTACT SOIL EXPOSURE  
FACTOR VALUES FOR THE COMMERCIAL AND INDUSTRIAL LAND USE  
CATEGORY

1. ( $ED_{\text{commercial/industrial}}$ ) Exposure Duration: This term is defined by a custom probability distribution based on the U.S. Bureau of Labor Statistics 2000 tenure data.

Years at One Job	Relative Probability
1	0.202
2 to 5	0.284
6 to 9	0.197
10 to 14	0.131
15 to 19	0.072
20 to 40	0.116

The relevant criterion for determining the Exposure Duration value is the length of worker's employment at a particular property. The available data set which was determined to best represent this term is employment tenure with a specific employer. The selected distribution is based on the data obtained through a Bureau of Labor Statistics survey which posed the questions from a sample of workers asking: (1) how old are you? and (2) how long have you been working at your present job? These survey results do not exactly satisfy the requirements of the Exposure Duration term. For instance it does not account for how much longer younger workers will stay at the present job; for older workers, this survey does not account for worker tenures at jobs previous to the present one. The distribution for the Exposure Duration term was derived, however, by using survey data for workers age 25 and older in all worker categories. The survey data for relatively young workers (ages 16-24) were not used because these workers were judged to be too transient to be representative of the chronically exposed worker population.

2. ( $EF_{\text{commercial/industrial}}$ ) Exposure Frequency: This term is defined by a triangular distribution based on climate patterns in different regions of Ohio, and assumptions about the vacation leave, sick leave, holidays, and part-time/full-time status accrued to workers.

*Pathway:                      Ingestion and Inhalation      Dermal Contact*

Maximum value:	290 days year <sup>-1</sup>	290 events year <sup>-1</sup>
Likeliest value:	214 days year <sup>-1</sup>	214 events year <sup>-1</sup>
Minimum value:	132 days year <sup>-1</sup>	132 events year <sup>-1</sup>

The maximum value assumes that a worker is present at the location of employment for 290 days per year (6 days per week for 50 weeks, subtracting out 2 week vacation time and 10 days heavy rain precluding outside work). This is applicable to a worker in southern Ohio who is not affected by extreme weather conditions like frozen conditions or snow cover during winter, but is affected by 10 days heavy rain per year. Climate data indicate that some southern counties in Ohio have no months with an average air temperature below 32°F and thus no days when frozen or snow-covered ground would preclude exposure.

The likeliest value assumes that a worker is present at the location for 214 days per year. This is based on a normal work schedule of 5 days per week for 52 weeks, subtracting out 10 days of vacation time, 6 days of holiday, 20 working days when frozen or snow-covered conditions preclude exposure, and 10 days when heavy rain precludes outdoor exposure. Climate data indicate that the number of months when the average monthly temperature is below 32°F varies across Ohio from none (southern counties) to 3 months (northern counties), with many counties indicating 2 months with an average monthly temperature of below 32° F. These data also indicate that Ohio generally has about 20 days per year during non-winter months with rainfall of 0.5 inch or more. Some of the frozen or snow covered days of these months may occur on weekends, holidays, vacation, or sick days. Similarly, some of the heavy rain incidents may occur on days or during parts of the day when the worker is not present at the property. Accordingly it was assumed that there would be 20 days of frozen ground and 10 days of heavy rain during which exposure would be precluded.

The minimum value assumes a part-time worker who works four days per week, 52 weeks per year (208 days) in the northern part of the state which experiences three months of frozen ground. Deductions from the 208 days of exposure were made for the frozen ground days (12 weeks × 4 days per week = 48 days) and 80% of the total number of vacation, holiday and rain days described for the likeliest scenario (0.8 × [10 days vacation + 6 days holiday + 20 days heavy rain] = 28 days). Thus, 208 days - 48 days - 28 days = 132 days.

3. (BW<sub>commercial/industrial</sub>) Body Weight: This term is defined by a normal distribution for a population composed equally of men and women from Finley, *et al.*, truncated at the lower end to represent a minimum weight of 45 kg deemed likely for commercial and industrial workers.

Arithmetic Mean:	71 kg
Standard Deviation:	15.9 kg
Minimum:	45 kg

Maximum: 115 kg

Reference: Finley, B., Proctor, D., Scott, P., Harrington, N., Paustenbach, D., and Price, P. (1994). Recommended distributions for exposure factors frequently used in health risk assessment. *Risk Analysis* 14(4):533-553. These values from Table II, for age > 18 years, both genders.

4. ( $IR_{soil_{commercial/industrial}}$ ) Daily Soil Ingestion Rate: This term is defined as the product of two distributions described in this document, Hourly Soil Ingestion Rate and Exposure Time as follows:

$$IR_{soil_{commercial/industrial}} = hIR_{soil_{commercial/industrial}} \times ET_{commercial/industrial}$$

The term Hourly Soil Ingestion Rate is defined as follows:

( $hIR_{soil_{commercial/industrial}}$ ) Hourly Soil Ingestion Rate: This term is defined by a uniform distribution of a range of hourly soil ingestion rates, based on the average range of results for adult daily rates found in the literature subsequently divided by 16 waking hours. This is done to take into account that workers are only present at the property for a portion of the day.

Minimum: (1/16) mg hour<sup>-1</sup>  
Maximum: (132/16) mg hour<sup>-1</sup>

Only three published studies have attempted to estimate adult soil ingestion rates. None of them have focused on adult worker receptor populations. In addition, the number of subjects analyzed was very low. The minimum daily soil ingestion rate of 0.5 mg day<sup>-1</sup> was converted to an integer value of 1.0 and then divided by 16 to equal 1/16 mg hour<sup>-1</sup>, the minimum hourly soil ingestion rate. The maximum daily soil ingestion rate of 132 mg day<sup>-1</sup> was derived by assuming a soil ingestion rate at the high rate of 330 mg day<sup>-1</sup> described by Stanek et al. (1997) as the 95<sup>th</sup> percentile soil ingestion rate using the *median* of the best four trace elements for 10% of the work days (29 days) and a higher average soil ingestion rate of 110 mg day<sup>-1</sup> for the remaining 261 days of the 290 day work year defined by the maximum Exposure Frequency ( $EF_{commercial/industrial}$ ) value. The maximum daily rate of 132 mg day<sup>-1</sup> divided by 16 to equal 132/16 mg hour<sup>-1</sup>, the maximum hourly soil ingestion rate.

References: Calabrese, E.J., Stanek, E.J., Gilbert, C.E., and Barnes, R.M. (1990). Preliminary adult soil ingestion estimates: results of a pilot study. *Regulatory Toxicology and Pharmacology* 12:88-95

Hawley, J.K. (1985). Assessment of health risk from exposure to contaminated soil. *Risk Analysis* 5: 289-302.

Stanek, E.J., Calabrese, E.J., Barnes, R., and Pekow, P. (1997). Soil ingestion in adults - results of a second pilot study. *Ecotox. Environ. Safety*. 36:249-257.

U.S. EPA (1997). *Exposure Factors Handbook*. EPA/600/8-89/043.

5. ( $ET_{\text{commercial/industrial}}$ ) Exposure Time: This term is defined by a custom distribution based upon best professional judgement.

0.90 relative frequency: 8 hours day<sup>-1</sup>  
0.10 relative frequency: 12 hours day<sup>-1</sup>

This distribution was based on the assumption that most workers are at the property for 8 hours per day, and that 10% of workers are present at the property for workdays as long as 12 hours.

6. ( $FI_{\text{commercial/industrial}}$ ) Fraction Ingested of Soil that is Contaminated;  
( $FC_{\text{commercial/industrial}}$ ) Fraction of Dermal Contacted Soil that is Contaminated;  
and ( $FI_{\text{inh commercial/industrial}}$ ) Fraction of Air Inhaled Containing Volatiles and Particulates from a Contaminated Soil Source that is Contaminated: These terms represent the proportion of all soil at a Property, ingested, dermally contacted and inhaled, by the receptor population described, which is contaminated by the chemical of concern. In the simplest interpretation, they represent the proportion of the soil at a Property which is contaminated by a chemical of concern. They are expressed as the fraction of the surface area of the Property which is represented by the identified area(s) for that chemical of concern and assumes random activity and exposure patterns for a particular receptor at a Property. Thus exposure to soil concentrations of a chemical of concern, as represented by the exposure point concentration determined from the analytical results from the soil samples in the identified area(s), is assumed to occur only for those parts of the Property where the chemical of concern has been identified and quantified. On a property-specific basis, the terms can be uniquely constructed for each chemical of concern, or groups of chemicals of concern which are associated with a particular identified area(s), in accordance with paragraph (D)(3)(b)(iv)(A) of rule 3745-300-09 of the Ohio Administrative Code. If these terms are determined separately for each chemical of concern, the terms determined for each chemical of concern must be determined on the basis of all identified areas on a Property for which the chemical of concern has been identified and from which the exposure point concentration has been determined. Alternatively, the terms determined on a Property-specific basis may consider the spatial distribution of the chemical(s) of concern and the receptor activity patterns on a Property; the derivation of such property-specific  $FI_{\text{commercial/industrial}}$ ,  $FC_{\text{commercial/industrial}}$ , and  $FI_{\text{inh commercial/industrial}}$  terms on the basis of receptor activity patterns and their relationship to the identified area(s) must be performed in accordance with paragraph (D)(3)(b)(iv)(B) of rule 3745-300-09 of the

Ohio Administrative Code. For purposes of the generic numerical direct-contact soil standards, these terms have been defined by a uniform distribution:

Minimum: 0.01 (unitless)  
 Maximum: 1.00 (unitless)

A uniform distribution assumes equal probability of all combinations of contamination and activity patterns upon a property. For purposes of the generic numerical direct-contact soil standards, these terms have been defined by a uniform distribution from which, for each iteration, a value is selected for the  $FI_{\text{commercial/industrial}}$  term; the correlation between the Fraction Ingested, Fraction Dermal Contacted and Fraction Inhaled terms was accounted for by setting the value for the  $FC_{\text{commercial/industrial}}$  and  $FI_{\text{commercial/industrial}}$  terms equal to the value selected from the  $FI_{\text{commercial/industrial}}$  distribution such that, for each iteration:

$$FI_{\text{commercial/industrial}} = FC_{\text{commercial/industrial}} = FI_{\text{commercial/industrial}}$$

In the course of performing a Property-specific risk assessment, distributions may be developed for each of the  $FI_{\text{commercial/industrial}}$ ,  $FC_{\text{commercial/industrial}}$  and  $FI_{\text{commercial/industrial}}$  terms. In this case, the selection of a value from a distribution for the  $FI_{\text{commercial/industrial}}$  term may be correlated to the selection of a value from the distributions for the  $FC_{\text{commercial/industrial}}$  and  $FI_{\text{commercial/industrial}}$  terms on a Property-specific basis in accordance with paragraph (D)(3)(b)(iv) of Rule 3745-300-09 of the Ohio Administrative Code.

7. ( $SA_{\text{commercial/industrial}}$ ) Skin Surface Area Exposed: This term is defined as the product of the two distributions described as follows, Total Skin Surface Area and Fraction Skin Surface Area Exposed:

$$SA_{\text{commercial/industrial}} = SA_{\text{total commercial/industrial}} \times fSA_{\text{exp commercial/industrial}}$$

These two distributions are described as follows:

- 7a. ( $SA_{\text{total commercial/industrial}}$ ) Total Skin Surface Area: This distribution is dependent upon the distribution for Body Weight ( $BW_{\text{commercial/industrial}}$ ) by means of a distribution of surface area to body weight ratios derived by Phillips *et al.* (1993), who observed a strong correlation between surface area and body weight. The total skin surface area for adults was calculated based on the following Equation:

$$SA_{\text{total commercial/industrial}} (\text{cm}^2) = x \text{ cm}^2 \text{ kg}^{-1} \times BW_{\text{commercial/industrial}} (\text{kg})$$

where, based on a correlation coefficient between the surface area to body weight ratio and body weight,  $x$  is selected from a distribution of surface area to body

weight ratios for male and female adults aged 18 years and older described as follows:

Minimum:	200 cm <sup>2</sup> kg <sup>-1</sup>
Mean:	284 cm <sup>2</sup> kg <sup>-1</sup>
Maximum:	351 cm <sup>2</sup> kg <sup>-1</sup>
Standard deviation:	28 cm <sup>2</sup> kg <sup>-1</sup>

The correlation coefficient of -0.841 for the relationship of adult surface area: body weight ratio to body weight was derived on the basis of personal communication with Phillips (1996).

Reference: Phillips, L.J., Fares, R.J., and Schweer, L.G. (1993). Distributions of total skin surface area to body weight ratios for use in dermal exposure assessments. *J. Expos. Anal. Environ. Epid.* 3:331-338.

Phillips, L.J. personal communication with Ohio EPA, 17 October 1996.

- 7b. (fSA exp<sub>commercial/industrial</sub>) Fraction Skin Surface Area Exposed: This term is defined by a triangular distribution based on best professional judgements concerning clothing and, consequently, the fraction of total skin surface area corresponding to exposed body parts. The minimum, likeliest and maximum values were determined using data describing the percentage of total body surface area by parts of the adult body in U.S.EPA (1997).

Minimum:	0.100
Likeliest:	0.160
Maximum:	0.175

Dermal contact is an event-driven pathway, assuming that single or multiple contact events with soil per day result in exposure to total dose. The quantification of exposure through the dermal contact pathway is therefore independent of the time spent in contact with soil.

The minimum value of 0.100 assumes that a worker is wearing long-sleeved shirt and pants and that the hands, head and neck are exposed.

The likeliest value of 0.160 assumes that a worker is wearing short-sleeved shirt and the forearms, hands, head and neck are exposed.

The maximum value of 0.175 assumes that a worker wears short pants, short-sleeved shirt and shoes, and that the head, neck, hands, forearms and one-half the legs are exposed for four months per year, and that the worker wears short-sleeved

shirt and that the forearms, hands, head and neck are exposed for eight months per year.

Reference: U.S. EPA (1997). *Exposure Factors Handbook*. EPA/600/8-89/043.

8. ( $AF_{\text{commercial/industrial}}$ ) Soil Skin Adherence Factor: This term is defined by a triangular distribution based on data from a broad range of activities from the following key studies: Holmes *et al* (1999); Kissel *et al.* (1996); and Kissel *et al.* (1998).

Minimum:	0.1	mg cm <sup>-2</sup>
Likeliest:	0.3	mg cm <sup>-2</sup>
Maximum:	0.5	mg cm <sup>-2</sup>

The minimum value represents central tendency weighted AFs for activities associated with lower soil contact rates that a worker may engage in.

The likeliest value combines central tendency and upper bound weighted AFs for a range of activities.

The maximum value combines upper bound weighted AFs with higher soil direct contact activities.

References: Holmes Jr., K.K., Shirai, J.H., Richter, K.Y., and Kissel, J.C. (1999). Field measurement of dermal soil loadings in occupational and recreational activities. *Environ. Res.* A80:148-157.

Kissel, J.C., Richter, K.Y. and Fenske, R.A. (1996). Field measurement of dermal soil loading attributable to various activities: implications for exposure assessment. *Risk Analysis* 16:115-125.

Kissel, J.C., Shirai, J.H., Richter, K.Y., and Fenske, R.A. (1998). Investigation of dermal contact with soil in controlled trials. *J. Soil Contam.* 7(6):737-752.

9. ( $IR_{\text{Inh commercial/industrial}}$ ) Inhalation Rate: This term is defined by a triangular distribution based on key studies summarized in the U.S. EPA *Exposure Factors Handbook* (1997) Table 5-23.

Minimum:	0.75 m <sup>3</sup> hour <sup>-1</sup>
Likeliest:	1.00 m <sup>3</sup> hour <sup>-1</sup>
Maximum:	1.90 m <sup>3</sup> hour <sup>-1</sup>

The selected distribution is based on the percentage of time that a worker spends on sedentary, light, moderate, and heavy activities. The inhalation rate varies with the activity level.

The minimum value is based on the average of male and female adult average activity-specific inhalation rates assuming one-half of the time at sedentary activities rate ( $0.5 \text{ m}^3 \text{ hour}^{-1}$ ), and one-half of the time at light activities rate ( $1.0 \text{ m}^3 \text{ hour}^{-1}$ ).

The likeliest value is based on the average of male and female adult average activity-specific inhalation rates assuming one-third of the time at sedentary activities rate ( $0.5 \text{ m}^3 \text{ hour}^{-1}$ ), one-third of the time at light activities rate ( $1.0 \text{ m}^3 \text{ hour}^{-1}$ ) and one-third of the time at moderate activities rate ( $1.6 \text{ m}^3 \text{ hour}^{-1}$ ).

The maximum value is based on the average of male and female adult average activity-specific inhalation rates, assuming one-third of the time at light activities rate ( $1.0 \text{ m}^3 \text{ hour}^{-1}$ ), one-third of the time at moderate activities rate ( $1.6 \text{ m}^3 \text{ hour}^{-1}$ ) and one-third of the time at heavy activities rate ( $3.2 \text{ m}^3 \text{ hour}^{-1}$ ).

U.S. EPA (1991). *Human Health Exposure Manual, Supplemental Guidance: Standard Default Exposure Factors*. OSWER Directive 9285.6-03.

12. (CF) Conversion Factor. Point value.

$\text{CF} = 1 \times 10^{-6} \text{ kg mg}^{-1}$

Reference: U.S. EPA (1989). *Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual, Part A*. EPA/540/1-89/002.

13. (VF) Volatilization Factor: This term is defined as a point value, which is calculated on a chemical-specific basis, according to the equation described in paragraph I.A.2 of Section I of this document. Calculation of the VF term requires chemical-specific values for:

$D_i$ : Diffusivity in air ( $\text{cm}^2 \text{s}^{-1}$ )  
 $H'$ : Dimensionless Henry's law constant  
 $D_w$ : Diffusivity in water ( $\text{cm}^2 \text{s}^{-1}$ )  
 $K_d$ : Soil-water partitioning coefficient ( $\text{cm}^3 \text{g}^{-1}$ )  
 $K_{oc}$ : Soil organic carbon-water partitioning coefficient ( $\text{cm}^3 \text{g}^{-1}$ )

as described by U.S. EPA (1996).

Reference: U.S. EPA (1996). *Soil Screening Guidance: Technical Background Document*. Section 2.4.2. Office of Solid Waste and Emergency Response. EPA/540/R-95/128. PB96-963502. May 1996. 168 pp. plus appendices.

14. (PEF) Particulate Emissions Factor: This term is defined as a point value calculated according to the methodology described in Section I of this document. It incorporates climate data from Cleveland, Ohio.

$$\text{PEF} = 1.68 \times 10^9 \text{ m}^3 \text{ kg}^{-1}$$

Calculation of this term on a Property-specific basis as described in the equation found in paragraph I.A.3 of Section I of this document and must be performed in accordance with paragraph (D)(3)(b)(iv)(A) of rule 3745-300-09 of the Ohio Administrative Code.

Reference: U.S. EPA (1996). *Soil Screening Guidance: Technical Background Document*. Section 2.4.5. Office of Solid Waste and Emergency Response. EPA/540/R-95/128. PB96-963502. May 1996. 168 pp. plus appendices.

DERIVATION AND JUSTIFICATIONS FOR THE DIRECT CONTACT SOIL  
EXPOSURE FACTOR VALUES FOR CONSTRUCTION OR EXCAVATION  
ACTIVITIES

1. ( $ED_{\text{construction/excavation}}$ ) Exposure Duration: Exposures during construction or excavation activities are generally for short durations as defined in rule 3745-300-08 of the Administrative Code.  
1 year.
2. ( $EF_{\text{construction/excavation}}$ ) Exposure Frequency: This term is defined by a triangular distribution based on a range of potential activities conducted by construction or excavation workers.

<i>Pathway:</i>	<i>Ingestion and Inhalation</i>	<i>Dermal Contact</i>
Maximum value:	250 days year <sup>-1</sup>	250 events year <sup>-1</sup>
Likeliest value:	120 days year <sup>-1</sup>	120 events year <sup>-1</sup>
Minimum value:	10 days year <sup>-1</sup>	10 events year <sup>-1</sup>

The minimum value represents short term construction or excavation activities including but not limited to maintenance and installation of utility lines, sewer maintenance, and small construction projects.

The likeliest value represents the majority of activities that occur during development and redevelopment activities at a property including but not limited to maintenance and installation of building footers and foundations, grading, and general construction on the property.

The maximum value represents larger scale development and redevelopment activities at a property including but not limited to the installation of building footers and foundations, grading, and general construction activities on the property.

3. ( $BW_{\text{construction/excavation}}$ ) Body Weight: This term is defined by a normal distribution for a population composed equally of men and women from Finley, *et al.*, truncated at the lower end to represent a minimum weight of 45 kg deemed likely construction and excavation workers.

Arithmetic Mean:	71 kg
Standard Deviation:	15.9 kg
Minimum:	45 kg
Maximum:	115 kg

Reference: Finley, B., Proctor, D., Scott, P., Harrington, N., Paustenbach, D., and Price, P. (1994). Recommended distributions for exposure factors frequently used in health risk assessment. *Risk Analysis* 14(4):533-553. These values from Table II, for age > 18 years, both genders.

4. ( $IR_{soil_{\text{construction/excavation}}}$ ) Daily Soil Ingestion Rate: This term is defined as the product of two distributions described in this document, Hourly Soil Ingestion Rate and Exposure Time as follows:

$$IR_{soil_{\text{construction/excavation}}} = hIR_{soil_{\text{construction/excavation}}} \times ET_{\text{construction/excavation}}$$

The term Hourly Soil Ingestion Rate is defined as follows:

( $hIR_{soil_{\text{construction/excavation}}}$ ) Hourly Soil Ingestion Rate: This term is defined by a uniform distribution of a range of hourly soil ingestion rates, based on the higher end of the results for adult daily rates found in the literature subsequently divided by 16 waking hours. This is done to take into account that workers are only present at the property while working.

Minimum:	(100/16) mg hour <sup>-1</sup>
Maximum:	(330/16) mg hour <sup>-1</sup>

Only three published studies have attempted to estimate adult soil ingestion rates. None of them contain data on soil ingestion rates for workers performing outdoor construction or excavation activities. As a result, best professional judgement was used to construct this distribution. A higher *average* soil ingestion rate of 100 mg day<sup>-1</sup> was used as the minimum value. The maximum value is based on the 95<sup>th</sup> percentile soil ingestion rate using the *median* of the best four trace elements reported by Stanek et al. (1997).

References: Calabrese, E.J., Stanek, E.J., Gilbert, C.E., and Barnes, R.M. (1990). Preliminary adult soil ingestion estimates: results of a pilot study. *Regulatory Toxicology and Pharmacology* 12:88-95

Hawley, J.K. (1985). Assessment of health risk from exposure to contaminated soil. *Risk Analysis* 5: 289-302.

Stanek, E.J., Calabrese, E.J., Barnes, R., and Pekow, P. (1997). Soil ingestion in adults - results of a second pilot study. *Ecotox. Environ. Safety*. 36:249-257.

U.S. EPA (1997). *Exposure Factors Handbook*. EPA/600/8-89/043.

5. ( $ET_{\text{construction/excavation}}$ ) Exposure Time: This term is defined by a custom distribution based upon best professional judgement.

0.90 relative frequency: 8 hours day<sup>-1</sup>  
0.10 relative frequency: 12 hours day<sup>-1</sup>

This distribution was based on the assumption that most workers are at the property for 8 hours per day, and that 10% of workers are present at the property for workdays as long as 12 hours.

6. ( $FI_{\text{construction/excavation}}$ ) Fraction Ingested of Soil that is Contaminated;  
( $FC_{\text{construction/excavation}}$ ) Fraction of Dermal Contacted Soil that is Contaminated;  
and ( $FI_{\text{inh}}_{\text{construction/excavation}}$ ) Fraction of Air Inhaled Containing Volatiles and Particulates from a Contaminated Soil Source that is Contaminated: These terms represent the proportion of all soil at a Property, ingested, dermally contacted and inhaled, by the receptor population described, which is contaminated by the chemical of concern. In the simplest interpretation, they represent the proportion of the soil at a Property which is contaminated by a chemical of concern. They are expressed as the fraction of the surface area of the Property which is represented by the identified area(s) for that chemical of concern and assumes random activity and exposure patterns for a particular receptor at a Property. Thus exposure to soil concentrations of a chemical of concern, as represented by the exposure point concentration determined from the analytical results from the soil samples in the identified area(s), is assumed to occur only for those parts of the Property where the chemical of concern has been identified and quantified. On a property-specific basis, the terms can be uniquely constructed for each chemical of concern, or groups of chemicals of concern which are associated with a particular identified area(s), in accordance with paragraph (D)(3)(b)(iv)(A) of rule 3745-300-09 of the Ohio Administrative Code. If these terms are determined separately for each chemical of concern, the terms determined for each chemical of concern must be determined on the basis of all identified areas on a Property for which the chemical of concern has been identified and from which the exposure point concentration has been determined. Alternatively, the terms determined on a Property-specific basis may consider the spatial distribution of the chemical(s) of concern and the receptor activity patterns on a Property; the derivation of such property-specific  $FI_{\text{construction/excavation}}$ ,  $FC_{\text{construction/excavation}}$ , and  $FI_{\text{inh}}_{\text{construction/excavation}}$  terms on the basis of receptor activity patterns and their relationship to the identified area(s) must be performed in accordance with paragraph (D)(3)(b)(iv)(B) of rule 3745-300-09 of the

Ohio Administrative Code. For purposes of the generic numerical direct-contact soil standards, these terms have been defined by a uniform distribution:

Minimum: 0.01 (unitless)  
 Maximum: 1.00 (unitless)

A uniform distribution assumes equal probability of all combinations of contamination and activity patterns upon a property. For purposes of the generic numerical direct-contact soil standards, these terms have been defined by a uniform distribution from which, for each iteration, a value is selected for the  $FI_{\text{construction/excavation}}$  term; the correlation between the Fraction Ingested, Fraction Dermal Contacted and Fraction Inhaled terms was accounted for by setting the value for the  $FC_{\text{construction/excavation}}$  and  $FI_{\text{construction/excavation}}$  terms equal to the value selected from the  $FI_{\text{construction/excavation}}$  distribution such that, for each iteration:

$$FI_{\text{construction/excavation}} = FC_{\text{construction/excavation}} = FI_{\text{construction/excavation}}$$

In the course of performing a Property-specific risk assessment, distributions may be developed for each of the  $FI_{\text{construction/excavation}}$ ,  $FC_{\text{construction/excavation}}$  and  $FI_{\text{construction/excavation}}$  terms. In this case, the selection of a value from a distribution for the  $FI_{\text{construction/excavation}}$  term may be correlated to the selection of a value from the distributions for the  $FC_{\text{construction/excavation}}$  and  $FI_{\text{construction/excavation}}$  terms on a Property-specific basis in accordance with paragraph (D)(3)(b)(iv) of Rule 3745-300-09 of the Ohio Administrative Code.

7. ( $SA_{\text{construction/excavation}}$ ) Skin Surface Area Exposed: This term is defined as the product of the two distributions described as follows, Total Skin Surface Area and Fraction Skin Surface Area Exposed:

$$SA_{\text{construction/excavation}} = SA_{\text{total, construction/excavation}} \times fSA_{\text{exp, construction/excavation}}$$

These two distributions are described as follows:

- 7a.  $SA_{\text{total, (construction/excavation)}}$  Total Skin Surface Area: This distribution is dependent upon the distribution for Body Weight ( $BW_{\text{construction/excavation}}$ ) by means of a distribution of surface area to body weight ratios derived by Phillips *et al.* (1993), who observed a strong correlation between surface area and body weight. The total skin surface area for adults was calculated based on the following Equation:

$$SA_{\text{total, construction/excavation}} (\text{cm}^2) = x \text{ cm}^2 \text{ kg}^{-1} \times BW_{\text{construction/excavation}} (\text{kg})$$

where, based on a correlation coefficient between the surface area to body weight ratio and body weight,  $x$  is selected from a distribution of surface area to body

weight ratios for male and female adults aged 18 years and older described as follows:

Minimum:	200 cm <sup>2</sup> kg <sup>-1</sup>
Mean:	284 cm <sup>2</sup> kg <sup>-1</sup>
Maximum:	351 cm <sup>2</sup> kg <sup>-1</sup>
Standard deviation:	28 cm <sup>2</sup> kg <sup>-1</sup>

The correlation coefficient of -0.841 for the relationship of adult surface area: body weight ratio to body weight was derived on the basis of personal communication with Phillips (1996).

Reference: Phillips, L.J., Fares, R.J., and Schweer, L.G. (1993). Distributions of total skin surface area to body weight ratios for use in dermal exposure assessments. *J. Expos. Anal. Environ. Epid.* 3:331-338.

Phillips, L.J. personal communication with Ohio EPA, 17 October 1996.

- 7b. (fSA exp<sub>construction/excavation</sub>) Fraction Skin Surface Area Exposed: This term is defined by a triangular distribution based on best professional judgements concerning clothing and, consequently, the fraction of total skin surface area corresponding to exposed body parts. The minimum, likeliest and maximum values were determined using data describing the percentage of total body surface area by parts of the adult body in U.S.EPA (1997).

Minimum:	0.100
Likeliest:	0.160
Maximum:	0.175

Dermal contact is an event-driven pathway, assuming that single or multiple contact events with soil per day result in exposure to total dose. The quantification of exposure through the dermal contact pathway is therefore independent of the time spent in contact with soil.

The minimum value of 0.100 assumes that a worker is wearing long-sleeved shirt and pants and that the hands, head and neck are exposed.

The likeliest value of 0.160 assumes that a worker is wearing short-sleeved shirt and the forearms, hands, head and neck are exposed.

The maximum value of 0.175 assumes that a worker wears short pants, short-sleeved shirt and shoes, and that the head, neck, hands, forearms and one-half the legs are exposed for four months per year, and that the worker wears short-sleeved

shirt and that the forearms, hands, head and neck are exposed for eight months per year.

Reference: U.S. EPA (1997). *Exposure Factors Handbook*. EPA/600/8-89/043.

8. ( $AF_{\text{construction/excavation}}$ ) Soil Skin Adherence Factor: This term is defined by triangular distribution based on data from a broad range of activities from the following key studies: Holmes *et al* (1999); Kissel *et al.* (1996); and Kissel *et al.* (1998).

Minimum:	0.3	mg cm <sup>-2</sup>
Likeliest:	0.7	mg cm <sup>-2</sup>
Maximum:	0.9	mg cm <sup>-2</sup>

The minimum value represents central tendency weighted AFs for activities associated with higher soil contact rates that a construction or excavation worker may engage in.

The likeliest value combines central tendency and upper bound weighted AFs for activities associated with higher soil contact rates that a construction or excavation worker may engage in.

The maximum value combines upper bound weighted AFs for activities associated with higher soil contact rates that a construction or excavation worker may engage in.

9. ( $IR_{\text{inh, construction/excavation}}$ ) Inhalation Rate: This term is defined by a triangular distribution based on key studies summarized in the U.S. EPA *Exposure Factors Handbook* (1997) Table 5-23 for outdoor workers.

Minimum:	1.1	m <sup>3</sup> hour <sup>-1</sup>
Likeliest:	1.5	m <sup>3</sup> hour <sup>-1</sup>
Maximum:	2.5	m <sup>3</sup> hour <sup>-1</sup>

The selected distribution is based on inhalation rates for slow, moderate and heavy activities. The minimum value represents the inhalation rate for slow activities; the likeliest value represents the inhalation rate for moderate activities; and the maximum inhalation rate represents the inhalation rate for heavy activities conducted by outdoor workers.

10. (ABS) Absorption Factor. Chemical-specific. Refer to Table I in Section I.

11. (AT) Averaging Time.

for Noncarcinogens:  $ncAT = ED \times 365 \text{ days year}^{-1}$

for Carcinogens (point value):  $cAT = 70 \text{ years} \times 365 \text{ days year}^{-1}$   
 $= 25550 \text{ days}$

U.S. EPA (1991). *Human Health Exposure Manual, Supplemental Guidance: Standard Default Exposure Factors*. OSWER Directive 9285.6-03.

12. (CF) Conversion Factor. Point value.

$CF = 1 \times 10^{-6} \text{ kg mg}^{-1}$

Reference: U.S. EPA (1989). *Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual, Part A*. EPA/540/1-89/002.

13. (VF) Volatilization Factor: This term is defined as a point value, which is calculated on a chemical-specific basis, according to the equation described in paragraph I.A.2 of Section I of this document. Calculation of the VF term requires chemical-specific values for:

$D_i$ : Diffusivity in air ( $\text{cm}^2 \text{ s}^{-1}$ )  
 $H'$ : Dimensionless Henry's law constant  
 $D_w$ : Diffusivity in water ( $\text{cm}^2 \text{ s}^{-1}$ )  
 $K_d$ : Soil-water partitioning coefficient ( $\text{cm}^3 \text{ g}^{-1}$ )  
 $K_{oc}$ : Soil organic carbon-water partitioning coefficient ( $\text{cm}^3 \text{ g}^{-1}$ )

as described by U.S. EPA (1996).

Reference: U.S. EPA (1996). *Soil Screening Guidance: Technical Background Document*. Section 2.4.2. Office of Solid Waste and Emergency Response. EPA/540/R-95/128. PB96-963502. May 1996. 168 pp. plus appendices.

14. (PEF) Particulate Emissions Factor: This term is defined as a uniform distribution. The minimum value represents the PEF calculated for wind erosion and for construction activities (e.g. dozing and grading activities) other than unpaved road traffic . The maximum value represents the PEF for unpaved road traffic. A uniform distribution was used to incorporate a range of possible scenarios.

Maximum: 7.74 E+05 m<sup>3</sup>/kg  
Minimum: 3.61 E+07 m<sup>3</sup>/kg

Calculation of this term on a Property-specific basis as described in the equation found in paragraph I.A.3 of Section I of this document must be performed in accordance with paragraph (D)(3)(b)(iv) of rule 3745-300-09 of the Ohio Administrative Code.

DERIVATION AND JUSTIFICATION OF EXPOSURE FACTOR VALUES FOR  
RESIDENTIAL POTABLE GROUND WATER USE SCENARIO

- 1a. ( $ED_{\text{potable-adult}}$ ) Exposure Duration: Adult: This term is defined by a custom probability distribution based on U.S. Census 2000 Supplementary Survey Summary Tables for the residency occupancy period data for Ohio.

Years at One Residence	Relative Probability
1	0.078
2 to 5	0.378
6 to 10	0.154
11 to 20	0.156
21 to 30	0.107
31 to 50	0.127

The selected distribution is based on data taking into account both rural and urban areas and both owner and renter occupied units.

- 1c. ( $ED_{\text{potable-child}}$ ) Exposure Duration: Child: This term is defined as a custom probability distribution based on U.S. Census 2000 Supplementary Survey Summary Tables for the residency occupancy period data for Ohio.

Years at One Residence	Relative Probability
1	0.078
2 to 5	0.378
6	0.544

The adult distribution was used for the child receptor except that all the probabilities above 6 years were truncated and added to the 6th year. If the simulation picks up a number higher than six years, then this distribution assures that a maximum of 6 years are accounted for a child.

- 2a. ( $EF_{\text{potable-adult}}$ ) Exposure Frequency: Adult: This term is defined by a triangular distribution based upon best professional judgement.

Maximum:	365 days year <sup>-1</sup>
Likeliest:	351 days year <sup>-1</sup>
Minimum:	323 days year <sup>-1</sup>

The maximum value assumes an adult receptor in the residential scenario who is home every day of the year.

The likeliest value assumes an adult in the residential scenario who is away from home 14 days per year, as in two weeks vacation.

The minimum value assumes an adult in the residential scenario 14 days away from home due to vacation, plus 28 additional days away per year due to additional vacation, weekends and business travel.

- 2c. ( $EF_{\text{potable-child}}$ ) Exposure Frequency: Child: This term is defined as a triangular distribution based upon best professional judgement.

Maximum:	365 days year <sup>-1</sup>
Likeliest:	351 days year <sup>-1</sup>
Minimum:	323 days year <sup>-1</sup>

The maximum value assumes a child receptor in the residential scenario at home every day of the year.

The likeliest value assumes a child receptor in the residential scenario away from home for a period equivalent to two weeks vacation (14 days) per year.

The minimum value assumes a child receptor in the residential scenario away from home for two weeks vacation, and an additional 28 days (4 weeks or 14 weekends), due to additional vacation, family visits and weekend travel.

- 3a. ( $BW_{\text{potable-adult}}$ ) Body Weight: Adult: This term is defined by a normal distribution for an equal population of men and women from Finley, *et al.* (1994).

Mean:	71 kg
Standard Deviation:	15.9 kg
Minimum:	32 kg
Maximum:	115 kg

The minimum body weight was truncated at the lower end of the distribution at 32 kg accounting for elderly residents who may weigh less than other adults considered in the industrial worker scenario.

- 3c. ( $BW_{\text{potable-child}}$ ) Body Weight: Child: This term is defined as a normal distribution based on data from the National Center for Health Statistics (1987).

Mean: 16.8 kg  
Standard deviation: 3.0 kg

A time-averaged distribution of childhood body mass was developed by probabilistic modeling of varying exposure durations (1-6 years) beginning at varying ages of onset (0.5-5 years of age). Body mass for males for each age was sampled based upon the above parameters from body mass distributions for each age selected and added in yearly increments over the selected exposure duration. The time-averaged body mass (kg) for each iteration was calculated by adding body mass for each year and dividing by the exposure duration (yrs). To ensure statistical integrity, male distributions were employed. Although actual values varied between genders, no significant differences were detected at the ages sampled (6 months - 5 years).

4a. ( $IR_{\text{potable-adult}}$ ) Tap Water Ingestion Rate: Adult: This term is defined by a lognormal distribution based on data from Ershow and Cantor (1989).

1 percentile value: 0.148 L day<sup>-1</sup>  
Median: 1.252 L day<sup>-1</sup>  
Mean: 1.366 L day<sup>-1</sup>  
99 percentile value: 3.780 L day<sup>-1</sup>

4c. ( $IR_{\text{potable-child}}$ ) Tap Water Ingestion Rate: Child: This term is defined by a normal distribution based on data from Ershow and Cantor (1989).

Mean: 0.685 L day<sup>-1</sup>  
Standard deviation: 0.276 L day<sup>-1</sup>

A time-averaged distribution of childhood drinking water ingestion rates was developed by probabilistic modeling of varying exposure durations (1-6 years) beginning at varying ages of onset (0.1-5 years of age). Drinking water rates for each age were sampled based upon the above parameters from drinking water ingestion rate distributions for each age selected and added in yearly increments over the selected exposure duration. The time-averaged rate ( $L\ day^{-1}\ year^{-1}$ ) for each iteration was calculated by dividing total consumption during the exposure duration by the exposure duration.

6a. ( $SA_{potable-adult}$ ) Total Skin Surface Area: Adult: This distribution is dependent upon the distribution for Body Weight ( $BW_{potable-adult}$ ) by means of a distribution of surface area to body weight ratios derived by Phillips *et al.* (1993), who observed a strong correlation between surface area and body weight. The total skin surface area for adults was calculated based on the following Equation:

$$SA_{total, potable-adult} (cm^2) = x\ cm^2\ kg^{-1} \times BW_{potable-adult} (kg)$$

where, based on a correlation coefficient between the surface area to body weight ratio and body weight,  $x$  is selected from a distribution of surface area to body weight ratios for male and female adults aged 18 years and older described as follows:

Minimum:	200 $cm^2\ kg^{-1}$
Mean:	284 $cm^2\ kg^{-1}$
Maximum:	351 $cm^2\ kg^{-1}$
Standard deviation:	28 $cm^2\ kg^{-1}$

The correlation coefficient of -0.841 for the relationship of adult surface area: body weight ratio to body weight was derived on the basis of personal communication with Phillips (1996).

Reference: Phillips, L.J., Fares, R.J., and Schweer, L.G. (1993). Distributions of total skin surface area to body weight ratios for use in dermal exposure assessments. *J. Expos. Anal. Environ. Epid.* 3:331-338.

Phillips, L.J. personal communication with Ohio EPA, 17 October 1996.

6c. ( $SA_{\text{potable/child}}$ ) Total Skin Surface Area: Child: This distribution is dependent upon the distribution for  $BW_{\text{potable-child}}$ , by means of two distributions of surface area:body weight ratios developed by Phillips, *et al.* (1993). These two SA:BW ratios were described for the age cohorts of 0 to 2 years and 2.1 to 17.9 years. Based upon the distributions for age of exposure onset, developed for the term  $IR_{\text{potable-child}}$ , and exposure duration for the child receptor,  $ED_{\text{potable-child}}$ , a value from the appropriate SA:BW distribution is selected, and total body surface area is thus derived for each value selected from the  $BW_{\text{potable-child}}$  distribution, by means of the equation:

$$SA_{\text{potable-child}} = x \text{ cm}^2 \text{ kg}^{-1} \times BW_{\text{potable-child}} \text{ (kg)}$$

The value for  $x$  is selected from the composite distribution for the SA:BW ratio for the age cohort 0.5 years to 6 years, (the age range of the child receptor in this potable ground water use scenario) which is described by the following distribution:

Minimum:	269 $\text{cm}^2 \text{ kg}^{-1}$
Mean:	453 $\text{cm}^2 \text{ kg}^{-1}$
Maximum:	1083 $\text{cm}^2 \text{ kg}^{-1}$
Standard deviation:	80 $\text{cm}^2 \text{ kg}^{-1}$

The distributions for  $BW_{\text{potable-child}}$  and the composite surface area:body weight ratio for children were related by a correlation coefficient of -0.734, based on personal communication with Phillips (1996).

Reference: Phillips, L.J., Fares, R.J., and Schweer, L.G. (1993). Distributions of total skin surface area to body weight ratios for use in dermal exposure assessments. *J. Expos. Anal. Environ. Epid.* 3:331-338.

Phillips, L.J. personal communication with Ohio EPA, 17 October 1996.

7. (PC) Dermal Permeability Coefficient of Chemicals in Water: This term is a chemical-specific point value for organic compounds, and a single point value for all inorganic compounds, as described below:

*Organic molecules:*

The values for PC were obtained as  $K_p$  values from Table 5-8 in U.S. EPA (1992), or derived by the following equation (Equation 5.11 in U.S. EPA, 1992):

$$\log K_p \text{ (cm hour}^{-1}\text{)} = -2.72 + 0.71 \log K_{o/w} - 0.0061 \text{ MW (daltons)}$$

where  $K_p$  = the permeability constant;  
 $K_{o/w}$  = the octanol/water partitioning coefficient; and  
MW = molecular weight.

*Inorganic molecules:*

The default value for inorganics recommended by U.S. EPA (1992) is:

$$K_p \text{ (cm hour}^{-1}\text{)} = 10^{-3} \text{ cm hour}^{-1}$$

Reference: U.S. EPA (1992). *Dermal exposure assessment: principles and applications, interim report*. Office of Research and Development. EPA/600/8-91/011B, January 1992.

8. (ET<sub>potable</sub>) Exposure Time for Daily Showering/Bathing: This term is defined as a point value.

$$\text{Point value: } 12 \text{ minutes day}^{-1} = 0.2 \text{ hour day}^{-1}$$

A study by James and Knuiman (1987) of 2500 Australian households reported that showering times ranged from 2 to 20 minutes, with a 90th percentile value of 12 minutes. For bath times, Brown and Hattis estimated dermal absorption from hypothetical bathtub scenarios and assumed a bath time of 20 minutes. Tarshis (1981) reported that 90% of Americans take some type of bath each day and 5% bathe more than once a day. Showering was described as the primary method of body cleaning for 75% of men and 50% of women. No data were found for children. The U.S. EPA (1989, p. 6-44) recommended 0.117 hour as a central tendency value and 0.2 hour as an upper-bound value for showering exposure time.

9. ( $CF_{\text{potable-dermal}}$ ) Conversion Factor for dermal contact with chemicals in water: This term is defined as the point value in U.S. EPA (1989, Exhibit 6-13).

$$CF_{\text{potable-dermal}} = 0.001 \text{ L cm}^{-3}$$

Reference: U.S. EPA (1989). *Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual, Part A.* EPA/540/1-89/002. December 1989.

- 10a,c.( $IR_{\text{inh,potable}}$ ) Inhalation Rate while Showering or Bathing

( $IR_{\text{inh,potable-child}}$ ): Point value:  $0.47 \text{ m}^3 \text{ hour}^{-1}$   
( $IR_{\text{inh,potable-adult}}$ ): Point value:  $0.80 \text{ m}^3 \text{ hour}^{-1}$

The point value for children is based on the likeliest inhalation rate as defined in the inhalation rate distribution for children in the residential land use scenario developed for direct contact soil standards, described elsewhere in this document.

The point value for adults is based on the likeliest inhalation rate as defined in the inhalation rate distribution for adults in the residential land use scenario developed for direct contact soil standards, described elsewhere in this document.

Reference: California Air Resources Board (1993). Measurement of breathing rate and volume in routinely performed daily activities. Human Performance Lab. Contract No. A033-205. June 1993. 185 pp.

11. ( $K_{\text{potable}}$ ) Volatilization Constant: This term is defined as a point value for all chemicals with a Henry's Law Constant greater than  $1 \times 10^{-5} \text{ atm m}^3 \text{ mol}^{-1}$  during showering (Andelman, 1990):

$$K_{\text{potable}} = 1.875 \times 10^{-3} \text{ (unitless)}$$

Reference: Andelman, J.B. (1990). Total exposure to organic chemicals in potable water. Chapter 20 in Cantor, K.P., Christman, R.F., Ram, N.M.(editors), Significance and treatment of volatile organic compounds in water supplies. Lewis Publishers. pp.485-504.

12. ( $CF_{\text{potable-inhalation}}$ ) Conversion Factor for inhalation of volatiles from potable water:  
This term is defined as a point value:

$$CF_{\text{potable-inhalation}} = 1000 \text{ L m}^{-3}$$

## Section III: Development of Generic Direct-Contact Soil Standards for Lead

Generic direct-contact soil standards were developed for many chemicals that are important and common contaminants at brownfield or similar sites. These standards were developed using target risk levels, toxicological data, exposure assumptions and modeling techniques described in Sections I and II of this document. Lead, however, is a unique chemical in that it has important noncancer adverse effects upon human health, but does not appear to have a threshold exposure level. Therefore, lead is generally evaluated somewhat differently than other chemicals.

There are no appropriate toxicological benchmarks (i.e., slope factor or reference dose) for lead. Rather, the generally accepted methodology for evaluating exposures to lead is the estimation of blood lead (PbB) concentrations from media exposures with a comparison to blood lead levels considered to be indicative of adverse health effects.

Using this approach, the Ohio EPA VAP has developed generic numerical direct contact soil standards for lead for three populations: a residential child, a commercial/industrial worker, and a construction worker. The derivations of these standards are described below. The information contained in these sections can also be used by volunteers or certified professionals who choose to evaluate lead in a property-specific risk assessment. Further information regarding lead modeling can be obtained from the U.S.EPA Technical Review Workgroup for Lead at the following website:

<http://www.epa.gov/superfund/programs/lead/>

### A. Derivation of a Generic Direct-Contact Soil Lead Standard for a Residential Child

The **generic numerical standard for direct contact soils, protective of a child in the residential land use category is 400 mg/kg**. This value is the U.S. EPA-recommended screening level for lead in residential soils. The value is recommended in two U.S. EPA documents providing interim guidance: 1) the Toxic Substances Control Act (TSCA) Section 403 guidance from the Office of Prevention, Pesticides, and Toxic Substances (U.S. EPA, 1994d) and 2) Office of Solid Waste and Emergency Response guidance (U.S. EPA, 1994c).

Children are regarded as a sensitive subpopulation with regard to lead toxicity. The U.S. EPA derived this recommended lead screening level by use of the Integrated Exposure Uptake Biokinetic Model (IEUBK) developed for children (U.S. EPA, 1994a,b; 2001). The model uses four interrelated modules to estimate blood lead (PbB) levels in children exposed to lead-contaminated media. The modules account for exposure, uptake, and the biokinetics of lead in the body and predict a probability distribution of PbB levels. From this distribution, the model estimates the risk that a child's PbB will exceed a level of concern,

which is typically considered to be 10 ug/dL. The basis of the 400 mg/kg screening level was the use of the IEUBK Model with default input values for physiological parameters (e.g., soil ingestion rates, absorption and bioavailability) and media concentrations (i.e., drinking water, air, diet, dust, etc.). Under these default conditions and including an approximately 400 mg/kg level of lead in soil, the model predicts that no more than 5% of the modeled population would exceed a target PbB of 10 ug/dL.

The VAP reevaluated the IEUBK model defaults (i.e., soil ingestion rates, dietary lead levels, etc.). In addition, model runs were evaluated assuming no more than 10% of a modeled population would exceed PbB concentrations of 10 ug/dL. Although the resulting soil concentrations varied somewhat (some higher, some lower), the variability in the modeling results was considered trivial and therefore 400 mg/kg has been retained as the generic direct contact soil standard for lead for residential land uses under the VAP.

Volunteers or Certified Professionals electing to perform a property-specific risk assessment for lead are required to use the IEUBK model to determine risks to children from exposures to lead. Changes to the U.S. EPA default values should, however, be approached with caution. Valid, defensible, site-specific information and monitoring data will be required by VAP to support any changes in the recommended default values.

## **B. Derivation of the Generic Direct-Contact Soil Standard for Lead for the Commercial and Industrial Land Use Categories**

The generic direct-contact soil standard for lead for the **commercial and industrial land use categories is 1,800 mg/kg**. This value was also derived using U.S. EPA methodology.

The U.S.EPA's Technical Review Workgroup for Lead has developed an approach for assessing risks associated with adult exposures to lead in soil and establishing cleanup goals that will protect adults and fetuses from lead in soil (U.S. EPA, 1996). This guidance does not recommend a specific target soil lead cleanup level, but proposes a methodology that allows for the input of either property-specific data or default values to assess risk and develop property-specific cleanup goals. The methodology is intended for use until an integrated exposure Biokinetic model for adults is developed by the U.S. EPA. Although it is acknowledged that other adult lead models are available and useable, the U.S.EPA concludes that this Adult Lead Model is the most appropriate methodology for modeling adult exposures to lead for scenarios, primarily occupational, where relatively steady patterns of exposure are or are expected to occur.

The VAP adopted the U.S. EPA's Adult Lead Model as its preferred methodology for calculating generic numerical standards for adult populations and recommends its use in any property-specific evaluation of lead risks for a number of technical reasons that include the following: 1) the inclusion of inter-individual variability within the exposed population; 2) the inclusion of assumptions regarding existing baseline blood lead levels; 3) the explicit

protection of the developing fetus of a worker as the most sensitive subpopulation; 4) the acceptance of the model's use in the scientific and regulatory communities; and 5) the level of peer review and technical support documentation developed for the model. The spreadsheets used by the VAP along with the technical documentation supporting the input parameters can be found on the U.S. EPA Technical Review Workgroup for Lead website;

<http://www.epa.gov/superfund/programs/lead/adult.htm>

### **Basis of the U.S. EPA Adult Lead Model:**

The primary assumption in the Adult Lead Model is that the receptor of concern in the workplace is the fetus. The methodology assumes that fetuses, like children, are more sensitive to the effects of lead in blood than are adults. The Adult Lead Model relates soil lead concentrations to PbB in the mother and the developing fetus based on the following assumptions: 1) expected fetal PbB levels are proportional to maternal PbB levels; 2) maternal PbB levels can be estimated as the sum of an expected initial PbB without property exposures and an expected property-related increase; 3) the property-related increase in maternal PbB can be estimated using a linear Biokinetic slope factor, multiplied by an estimated lead uptake; 4) lead uptake can be estimated based on concentrations of lead in soil by assuming an adult soil ingestion rate and an estimated absorbed fraction of ingested lead from the soil; and 5) the distribution of PbB levels in a given adult population who contact similar levels of lead in soil is lognormal.

A standard for lead in soil can therefore, be calculated (using the Adult Lead Model) that corresponds to a specific acceptable PbB in mothers and fetuses. This can be done by using either property specific or default exposure assumptions. The acceptable blood lead distribution used by the VAP was set such that at least 90 percent of the fetuses in a population of women are predicted to have PbB levels of 10 ug/dL or less. The 90th percentile is the level of protection assumed for all VAP generic numerical standards (GNSs).

### **U.S. EPA Adult Lead Model Methodology:**

The U.S. EPA Adult Lead Model estimates the geometric mean blood lead concentration in adults based on soil lead concentrations using the following equation:

$$PbB_{GM} = PbB_0 + \left( \frac{Pb_s * BKSF * IR_s * AF_s * EF_s}{AT} \right) \quad \text{Equation 1}$$

Where:

- $PbB_{GM}$  = Geometric mean estimate of blood lead concentrations in adults (i.e., women of child-bearing age) that have site exposures ( $\mu\text{g/dL}$ ).
- $PbB_{adult,0}$  = Baseline blood lead concentrations in women of child-bearing age in the absence of exposures at the property ( $\mu\text{g/dL}$ ).
- $Pb_s$  = Average soil lead concentration ( $\mu\text{g/g}$ ).
- BKSF = Biokinetic slope factor relating increase in typical lead level to average daily uptake of lead ( $\mu\text{g/dL}$  blood lead increase per  $\mu\text{g/day}$  lead uptake).
- $IR_s$  = Intake rate of soil, including soil contained in indoor dust (g/day)
- $AF_s$  = Absolute gastrointestinal absorption fraction for ingested lead in soil and dust (unitless).
- $EF_s$  = Exposure frequency for contact with soils and/or dust (days/year)
- AT = Averaging time (365 days/year)

Equation 1 can be rearranged to calculate the soil standard (or concentration) associated with a given exposure scenario and target adult blood lead concentration distribution, resulting in Equation 2:

$$GNS = Pb_s = \frac{(PbB_{adult,central,goal} - PbB_{adult,0}) * AT}{(BKSF * IR_s * AF_s * EF_s)} \quad \text{Equation 2}$$

The following equation is used to calculate  $PbB_{adult,central,goal}$ :

$$PbB_{adult,central,goal} = \frac{PbB_{fetal,0.90,goal}}{GSD^{1.282} * R} \quad \text{Equation 3}$$

Where:

- $PbB_{\text{fetal},0.90,\text{goal}}$  =Goal for the 90th percentile blood lead concentration (ug/dL) among fetuses in a population of exposed women. The goal is intended to ensure that  $PbB_{\text{fetal},0.90,\text{goal}}$  does not exceed 10 ug/dL.
- R =Constant of proportionality between fetal and maternal blood lead concentration (dimensionless).
- $GSD_i$  =Estimated value of the individual geometric standard deviation among women of child-bearing age in the exposed population. This value represents the expected variation in blood lead levels from a population of women that have exposures to similar property-specific lead concentrations, but have a nonuniform response (intake, absorption, biokinetics) to lead exposures and nonuniform off-property lead exposures. The exponent, 1.282, is the value used to calculate the 90th percentile from a lognormal distribution of blood lead concentration.

### **Selection of Model Parameter Inputs:**

The U.S. EPA Adult Lead Model guidance recommends the use of site-specific data in the model wherever feasible and recommends default values when site-specific information is not available (U.S. EPA, 1996). In the calculation of the GNS for lead, the VAP used default values either recommended by U.S. EPA, or exposure factors used in the derivation of GNSs for other chemicals. The parameter values selected are described as follows:

#### Target 90th Percentile Fetal Blood Lead Concentration ( $PbB_{\text{fetal},0.90,\text{goal}}$ )

The weight-of-evidence from the scientific literature suggests that delayed or impaired neurodevelopment during the first 12 months of postnatal life can be associated with maternal blood lead levels during pregnancy or neonatal blood lead levels at birth (U.S. EPA, 1996). The scientific literature evaluating maternal blood lead concentrations associated with adverse effects on the fetus is not as well documented. To account for this uncertainty, a **fetal blood lead level of 10 µg/dL** was selected by U.S. EPA for use in the Adult Lead Model, based on the assumption that the blood lead level of concern for fetuses is the same as that for children. Using the U.S. EPA-recommended value of **0.9 for R**, a fetal blood lead level of 10 µg/dL is associated with a maternal blood lead level of 11.1 µg/dL.

### Constant of Proportionality Between Fetal and Maternal Blood Lead Concentration (R)

The U.S. EPA has recommended a **fetal/maternal blood lead ratio of 0.9**, based on weight-of-evidence from studies that have explored the relationship between cord and maternal blood lead. The strongest evidence supporting this value is from a study by Graziano et al. (1990) comparing maternal blood lead and umbilical cord blood lead at delivery in 888 mother-infant pairs between 28 and 44 weeks of gestation. The relationship between maternal blood lead and umbilical cord blood lead in this study was linear with a slope of 0.93; the correlation coefficient was 0.92.

### Individual Blood Lead Geometric Standard Deviation (GSD<sub>i</sub>):

The U.S. EPA acknowledges that there is uncertainty associated with this parameter and recommends that site-specific blood lead data be collected wherever possible. Since this is not possible in the development of a generic standard, the U.S. EPA-recommended **default of 2.0** was used in the GNS derivation (U.S. EPA, 1999). This value represents the approximate midpoint from the plausible range of values of 1.8 to 2.1. The 1.8 value represents the GSD<sub>i</sub> for homogenous populations, and 2.1 represents the GSD<sub>i</sub> for diverse, urban populations. This information is from an analysis of blood lead concentration data collected in the NHANES III data collection effort (Brody et al., 1994).

### Baseline Blood Lead Concentration (PbB<sub>0</sub>)

The U.S. EPA recommends PbB<sub>0</sub> (µg/dL) values of 1.7 for whites, 2.0 for Hispanics, and 2.2 for blacks. These recommendations are a result of the analysis of NHANES III data collected and evaluated by Brody et al. (1994). The higher blood lead values for black and Hispanic females may be related more to socioeconomic factors such as place of residence than to actual racial differences (e.g., lead in soil and dust is higher in urban areas than in rural areas, because lead from automobile exhaust and lead-based paint has had a greater impact on soil and dust in urban areas).

For the GNS calculation, the approximate midpoint of the recommended range of PbB<sub>0</sub> was selected (**2 µg/dL**). This is the recommended U.S. EPA default for evaluation at sites where the population demographics are unknown (U.S. EPA, 1999).

### Biokinetic Slope Factor (BKSF):

The U.S. EPA recommends a **BKSF of 0.4** (µg/dL per µg lead uptake from water/day) for adults based on an evaluation of Pocock et al. (1983). This value is based on the assumption (derived from the Pocock analysis) that the slope factor for lead ingested in water is 0.09 (µg/dL per µg lead ingested in water/day) and the fraction of lead absorbed from water by pregnant women ranges from 0.20 to 0.25. The BKSF for lead uptake from water was back calculated: 0.4 µg/dL per µg lead uptake/day = (0.09 µg/dL per µg lead ingested/day)/0.20.

Bowers et al. (1994) derived a similar BKSF of 0.375 µg/dL per µg lead uptake/day. This analysis used the same data set as Pocock et al. (1983), but with different assumptions and without the adjustments for a mixture of first draw and flushed water intake assumed in the Pocock et al. (1983) study.

#### Daily Soil Ingestion Rate (IRs):

The U.S. EPA recommends a **default value of 0.05 g/day** as a plausible point estimate for average daily soil intake from all occupational sources, including soil in indoor dust. This is representative of noncontact-intensive activities, which would be reasonably expected at most VAP properties. This value is also the U.S. EPA standard default for average (central tendency) occupational exposures (U.S. EPA, 1993).

#### Absolute Gastrointestinal Absorption Fraction for Ingested Lead in Soil and Dust (AFs).

The U.S. EPA recommends a default value of 0.12 as an estimate of the fraction of lead in soil ingested daily that is subsequently absorbed by the gastrointestinal tract. This value is based on assumptions regarding the gastrointestinal absorption of soluble lead and the relative bioavailability of lead in soil compared to soluble lead.

A **default value of 0.2 for absorption of soluble lead** is based on a U.S. EPA weight-of-evidence approach that evaluated experimental results of bioavailability of ingested lead in adult humans, considering variability in food intake and lead intake. In the absence data regarding different species of lead and particle sizes, the U.S. EPA considers 0.6 to be a plausible default point estimate for relative bioavailability based on experimental studies (Weis et al. 1994; Maddaloni et al. 1996).

The **default value of 0.6 for relative bioavailability of lead** in soil compared to soluble lead coupled with the default value of 0.2 for the absorption factor for soluble lead results in a **soil absorption factor of 0.12 (0.6 \* 0.2)**. The U.S. EPA considers this value to be a plausible point estimate for use in assessments where site-specific information on lead bioavailability is not available.

#### Exposure Frequency (EF<sub>s</sub>):

The exposure frequency used is **214 days**. This is the likeliest value from the distribution used by the VAP in the development of GNS values for other chemicals. This value is similar to U.S. EPA-recommended default value of 219 days/year.

#### Averaging Time (AT):

An **averaging time of 365 days** is recommended by U.S. EPA. This default assumption represents sufficient time for the PbB to reach quasi-steady state conditions.

### **C. Derivation of the Generic Direct-Contact Soil Standard for Lead for Construction or Excavation Activities**

The U.S. EPA Adult Lead Model described above for the commercial and industrial land use categories was similarly used for the development of a generic direct-contact soil standard for lead of **1,600 mg/kg for construction or excavation activities**. The following parameters were modified for the construction or excavation activities to reflect differences in assumed exposures. The other input assumptions not described below are the same as those used for the commercial and industrial land use categories.

#### Daily Soil Ingestion Rate (IRs):

There is a considerable lack of reliable scientific information regarding adult soil ingestion rates for intensive soil contact scenarios. Given that the model inputs should be based on central tendency estimates, the U.S. EPA recommends an appropriate default soil ingestion rate for construction worker scenarios of **100 mg/day** (U.S. EPA, 1999).

#### Exposure Frequency (EF<sub>s</sub>):

In developing GNS values for the construction worker, the VAP assumed a triangular distribution for exposure frequency. The likeliest value assumed in this distribution is 120 days. The U.S. EPA Adult Lead Model recommends the use of central tendency values, therefore, **120 days** is the EF<sub>s</sub> assumed in the calculation of a construction worker lead GNS.

### **D. Property-Specific Lead Evaluations for Adult Populations:**

The VAP recommends that Volunteers or Certified Professionals electing to perform a property-specific risk assessment for lead, use the U.S. EPA Adult Lead Model described above to assess risks to adults from exposures to lead. Use of other, similar models for the evaluation of adult exposures may be considered based on property-specific conditions.

Changes to the default values assumed by the VAP should, however, be approached with caution. Valid, defensible, site-specific information and monitoring data will be required by VAP to support any changes in the recommended default values per rule 3745-300-09 of the Ohio Administrative Code.
